Preface

We aim to provide most (we don't provide any information on how to be a therapist or guide) of the "full stack" of knowledge needed to successfully do MDMA therapy.

The process of memory reconsolidation has the potential to heal not just mental illness, but a wide range of maladaptive patterns ranging from the implicit biases partially driving some toxic politics, to insecurity, escapism, disconnection, and more. Traditional psychotherapy strongly relies on the client finding a practitioner they match well with, is expensive, has trouble making progress in the presence of strong resistance, dissociation, or panic, has significant drop-out rates, and frequently doesn't work. The psychedelic-therapy renaissance has emerged partly as a response to these challenges. While we believe a variety of psychedelics have positive roles to play in therapy, we focus on MDMA because of our personal experience and MDMA's relative ease of use for those with trauma.

Our deepest desire in this work is aiding the wellbeing and cooperation of all beings through the unlearning of maladaptive emotional learnings and practicing compassion. However, we have our own maladaptive beliefs, and may have projected them into this work in unhelpful ways despite attempting to correct for that. We've tried to be critical of the things we're enthusiastic about, but inevitably our biases have pushed us to be overly critical of some things and credulous about others. We try to strike a balance between practical applicability and scientific robustness but recognize that that balance means this document is optimally adapted to neither case. In addition, the scope of this document presents some problems. We have expertise in some aspects of MDMA-therapy, but are not research experts on a majority of the individual pieces of this document. Hence, while we have done our best to critically evaluate the evidence and our references, we will certainly have missed some nuances only visible to certain subject matter experts. Our core assumptions and our confidence for them are laid out in the introduction. The core ideas of the guide are likely solid, however, some of our citations will inevitably not reproduce in further experiments. Reproducible science is difficult to do and hard to identify.

The length, information-density, and technicality of this guide may make it mostly appealing to those who are highly motivated and have higher levels of education or a strong ability to self-educate. We felt this "full strength" version of the guide was important to write before attempting to make a more accessible version, as the knowledge from writing the full version is a prerequisite. Technical systematizing is also the only kind of writing MG knows how to do well. We're sorry if that doesn't work well for you!

Multiple psychedelic-therapy training programs exist for mental health professionals but typical therapist education often contains major oversights, and we strongly suspect psychedelic-therapy training programs do too. These programs are also locked behind pay-

walls. There are various solo MDMA-therapy guides that, while offering some valuable advice, are also full of poor-quality information and fail to adequately discuss safety risks. We attempt to fill the niche of accessible and practically applicable recommendations backed by rigorous scientific research, professional therapist experience, and strict ethical guidelines. Our experiences with the failure of the mental health treatment system help us tailor this document to the complex nuances of real situations. We are not aware of any other work that rigorously (highly systematized and epistemically grounded in neuroscience) covers a major part of "full stack" of knowledge required for successful MDMA therapy.

Mark Groeneveld: During my own use of MDMA-therapy I had a very difficult time figuring out what mental illness is, what MDMA-therapy does, and how to optimize MDMA-therapy for efficacy and safety. As I learned, rigorous answers to these questions have only started to appear in the 2000's and 2010's, and haven't yet widely diffused out of academia to on-the-ground practitioners or even therapist training programs. This knowledge base is also widely distributed in the research literature, and as far as I can tell, hasn't been put together in one place before, especially one accessible to a significant portion of the general public. This is unfortunate because many people are desperate for mental health treatment and are attempting MDMA-therapy with inadequate information. I thought a manual could help with these problems. My goal is for this document to be a comprehensive overview and self-contained starting point, including scientific descriptions of the core concepts and brief tutorials on a variety of related practices. Links to in-depth resources are provided for those wanting to dig deeper. This document aims to describe how the mind responds to trauma and how healing works, in a way that is hopefully clear, accurate, and directly applicable to healing. I hope you find it of use.

MG would like to thank: MDMA-therapy, for giving me hope. The scientists and therapists who developed this body of knowledge and practice. My friend Jessica Sojorne Libere, for MDMA-therapy guidance. My partner for encouragement, support, and editing. [r/mdmaththerapy](#) for numerous case examples.

Thomas Harper:

Author Contributions: MG developed the initial concept and first draft. TH and MG then shared writing, editing, concept development, and research. Total contribution of hours was about 75% MG and 25% TH. TH wrote the sections How to Find a Skilled and Well-Matched Therapist or Guide, most of Professional Guidance vs. Self Guidance, Organizing Community Care, Making Positive Life Changes, Prompts for Uncovering Common Maladaptive Schemas, Attachment Theory, and some odds-and-ends. MG wrote most of the rest. We shared editing equally.

Biases, Conflicts of Interest, and Author Background: See Table 1.

Chapter 1

**Introduction and Background

1.1 Executive Summary

1.2 The Essentials

This document is quite lengthy and not everyone has the time, energy, or motivation to read it all. Here are the essential sections:

- What is [Trauma](#) and Why do its Effects Stick Around ([2.3](#)), [Defense Cascade](#) ([2.2](#)), and Mechanism of Healing ([2.4](#))
- The first list in the safety section summarizing risks ([3.1](#)) and Professional Guidance vs. Self Guidance ([3.2](#))
- Dosing ([3.4](#)), Handling [Dissociation](#) and [Avoidance](#) During the Session ([3.5](#)), Pre-Session Preparation ([3.7](#)), The MDMA Therapy Session ([4.1](#)), and Troubleshooting ([4.2](#))

We also had good results (low rate of hallucinations, accurate, clear, helpful) getting the Claude 3.7 (We had much worse results with ChatGPT.) large language model to answer questions about this document using these instructions: "You should helpfully answer the user's questions about MDMA-therapy based on the attached document. The user may not understand the technical content of the paper, so you should make it easier to understand when appropriate. Feel free to interpolate/extrapolate the information in the document and make reasonable assumptions; you don't need to regurgitate it verbatim. Don't say 'the document says/recommends/presents/etc.,' that is assumed." Removing the bibliography from the PDF before uploading it will reduce the document size and allow you more questions before you hit the usage limits.

1.3 Introduction

MDMA creates powerful feelings of compassion, connection, and safety [[104](#)]. When used with skill, these emotional states are highly effective tools for healing and adaption. However, there are no quick fixes for all but the most simple issues. In our experience, even

in optimal conditions, MDMA-therapy and the best cases of traditional psychotherapy can take multiple years to heal severe mental illness. Additionally, almost all models of MDMA-therapy currently under investigation emphasize the necessity of between-session therapy or at-home therapeutic exercises, sometimes termed integration, to fully treat complex mental illness [28]. We think MDMA can provide an on-ramp to these activities if they have traditionally been difficult or useless for you. Uncovering and healing the effects of [trauma](#) can be psychologically [destabilizing](#) until the newly-surfaced emotions have been processed [226]. Therapeutic destabilization can be intense for those with the severe trauma [202]. We believe MDMA-therapy presents a significant increase in the potential cost-quality curve of therapy and provides a much needed tool for cases that haven't responded well to other approaches [212]. Various fundamentally similar framings highlight the potential benefits of therapy to different audiences:

- Healing mental illness or addiction
- Connecting to yourself, those you love, and the world.
- Developing equanimity, patience, compassion, introspection, resilience, alignment of behavior with goals, and cognitive and emotional flexibility.
- Unburdening from hyper-vigilance, fear, chronic stress, loneliness, addiction, shame, guilt, etc.
- Helping you focus on the things that you can change and let go of the things you can't.

Put another way, we think the processes in this document (also achieved through the best cases of traditional psychotherapy) can help you achieve the following characteristics of securely attached adults, developed by D. P. Brown and Elliott [43]:

Seeks emotional closeness with others; Able to establish emotional intimacy; Comfortable with mutual dependence; Comfortable being alone; Positive self-image and other image; Warm and open with others; Accepts criticism without significant distress; Strong sense of self; Self-esteem; Self-observational skills; Self-reflective skills; Able to trust in relationship; Relationships tend to be stable, lasting; Open with others about feelings; Positive feelings about relationships; Balanced experience of emotions-neither too little nor too much; Values attachment

The core process of healing is conceptually simple: activate a maladaptive pattern; contradict that pattern (with other knowledge, the present moment, or MDMA-induced feelings) until the pattern dissipates; repeat until satisfied [85]. Almost all of this manual is just instructions on how to facilitate this process with MDMA or other techniques, and how to manage support for yourself during the longer process of healing.

This manual has three use cases: mental health professionals seeking a thorough understanding of MDMA, mental health professionals seeking a supplementary resource to give to their clients, and people doing solo MDMA-therapy. Because of the complexities and risks of the practice, we generally recommend starting MDMA-therapy with professional assistance. However, availability, cost, or trust obstacles often make adequate professional assistance

hard to access and many people have to make the best of non-optimal circumstances. We think of this work as similar to "Where there is no Doctor."

This guide doesn't offer personalized medical advice, guarantee healing, assure the prevention of negative outcomes, or prevent legal problems if used in a place where MDMA is illegal. Instead, this guide presents a framework for increasing the efficacy and safety of MDMA-therapy, grounded in research, community insights, and author experiences. While this guide has universal aspects, it doesn't cover all frameworks for MDMA-therapy. Although MDMA-therapy has been practiced by underground therapists for decades, comprehensive scientific study is relatively recent, leaving some aspects unexplored [230]. Possessing [psychedelics](#) is a felony in many jurisdictions; this guide doesn't endorse illegal activities [238]. Licensed mental health professionals theoretically risk their licensure by offering psychedelic therapy in contexts where it isn't legal. In practice, we are only aware of two instances of this happening, both involving inappropriate therapist-client boundary crossing [182, 272].

As of the early 2020's, we are in a psychedelic hype bubble [324]. There are many reports and anecdotes of psychedelics treating a wide variety of health conditions. The hype bubble makes it difficult to figure out which are true and which are false. There are also many claims of psychedelics solving a wide variety of issues including war and oppression. We don't believe that just taking the medicine will necessarily change people's beliefs and actions related to these issues. However, we do suspect the fear partly driving these problems can be unlearned by explicitly activating the associated feelings during an MDMA session.

In 2024 the FDA declined to approve MDMA assisted therapy at the current time and requested more data. We recommend Evans [97] for a balanced analysis of why the FDA requested Lykos' do another study before reviewing the MDMA drug application again. Poor data collection and study design at MAPS and confusion at the FDA seem to be primary factors; not necessarily poor efficacy or safety, though a better trial could show worse efficacy or safety. E. Schenberg [266] also analyzes why a Dutch government commission decided there was enough evidence of efficacy and safety to legalize MDMA-therapy when the FDA did not. E. E. Schenberg et al. [267] also discusses how the FDA may have rejected the application because 1) the FDA's process is only capable of evaluating the effect of a drug alone, and can't evaluate the combined drug-therapy intervention 2) the FDA advisory committee didn't have the appropriate expertise to evaluate the application.

The writing process involved a back-and-forth combining of informal literature review with professional and personal experience. This was also informed by numerous self-reports of MDMA-induced adverse experiences. We resort to many "we suggest"s based on our personal and professional experience because the scientific literature on MDMA and psychotherapy is highly inadequate to the task of saying "this is the best way to do things based on rigorous evidence" for every detail of the process.

We avoid providing a simple list of instructions to follow because the practice of MDMA-therapy is sometimes complex, we are not able to provide individualized medical advice, and many uncertainties about the practice remain unresolved.

There is a glossary after the appendices. We used a script to link the first occurrences of glossary terms in each section to the glossary. This worked well, but there may an occasional inappropriately-linked term.

1.4 Background, Goals, and Rationale

Mental illness is one of the largest causes of suffering [318]. Besides being painful, difficult, and expensive for the people who experience it, it carries a heavy economic, emotional, and logistical cost for close companions of those who experience it. On top of all this, we hypothesize that the widespread prevalence of mental illness effects such as cognitive distortion, emotional rigidity, and emotions of deep insecurity and threat may be among the engines driving tribalism and political polarization across the globe. Even when mental illness isn't a factor in tribalism, we think that the learned maladaptive and false beliefs that are key components of humanity's tribalistic tendencies [162] can be unlearned by the same mechanism that mental illness can be unlearned. While a small number of individuals are able to access effective mental healthcare, both access and effectiveness are inadequate for most of the vast and growing population of individuals who experience mental illness.

We are developing an evidence based user guide to therapeutic MDMA use. Therapeutic use of MDMA is one of the most promising developments in psychopharmacology [212]. This guide has the potential to meaningfully reduce mental illness by addressing several of the most prevalent, highest impact barriers to effective care. By doing this, we hope to:

- Alleviate suffering
- Assist individuals in building their capacity to function effectively in the world.
- Increase the ability of individuals to feel and behave compassionately toward all beings.

Ultimately, we believe this has the potential to improve the capacity of entire communities to act collaboratively towards constructive ends. Although the usefulness of therapeutic MDMA for individuals who do not experience mental illness has not been established with the same research base, we are also hopeful that it could eventually become a resource for anyone who wishes to experience a greater sense of meaning, connection, and fulfillment in their life. We believe this guide provides the foundational knowledge necessary to leverage MDMA to create transformative increases in compassion and connectedness, relevant to many positive social outcomes as well as to mental healthcare. This project aims to amplify the broad-scale effectiveness of therapeutic MDMA use by helping overcome three categories of barriers:

- **Trust:** Feelings of trust towards the therapeutic process are an important resource for getting individuals into mental health treatment who need it, and feelings of trust between therapists and clients are an essential mechanism for the effectiveness of therapy [319]. One of the most exciting aspects of therapeutic MDMA usage is that it allows [traumatized](#) individuals to experience a sense of safety and connectedness that is otherwise physiologically and psychologically inaccessible to them, even in trust-worthy circumstances [104]. Additionally, many cultures and subcultures experience a normalized hostility regarding even the acknowledgement of mental illness, creating a challenge for clients who are in need of care and for clinicians who attempt to provide effective care in these communities. It can also be extremely difficult for individuals of a particular identity group to feel trust towards a clinician who shares few of their identities and little of their direct experience. Because of this, the ability to achieve

that trust more reliably with the support of MDMA may be an enormous asset in increasing the accessibility of effective care. Because of its emphasis on rigor and accessibility, the guide we are producing has the potential to increase the comfort of a wide variety of individuals who would not otherwise be willing to use MDMA, and the comfort of a wide variety of clinicians who would not otherwise be willing to support them.

- **Financial and logistical:** We believe MDMA is useful for increasing cost-effectiveness for many clients. This can happen through increased efficiency of therapy—it has already shown promise in clinical trials for treating cases resistant to conventional methods. It can also happen through gradually shifting a large amount of therapeutic work to at-home sessions the client conducts by themselves or with a “sitter” who needs far less training than a fully licensed clinician, if such a method is found to be safe and effective within certain parameters (as some underground practitioners we know have already anecdotally seen, and has been reported by Colbert and S. Hughes [63] and Hills [140]). We believe MDMA-assisted psychotherapy will make significant improvements to the cost/quality curve of psychotherapy.
- **Clinician training:** In our professional experience, many licensed clinicians lack access to the best and most up-to-date training on a variety of therapies because of financial barriers. Additionally, because MDMA usage is and has long been illegal, clinicians who ask their supervisors and senior colleagues about how to support this form of clinical work are often rebuffed. Many clinicians are unwilling to provide clinical support to individuals who embark on its therapeutic use on their own, due to this lack of training and support, as well as due to the legal ambiguities of such care. Depending on how flexible the FDA rules for clinical support are when and if MDMA is legalized, it is possible that providing a high quality open access manual at this early stage of the legalization process could have a positive impact on the culture of mental health providers around MDMA support. This has the potential to prevent rent-seeking experts from making an expensive certification the standard in clinical MDMA support before widespread access to therapeutic MDMA can even be established.

We are writing a rigorous, comprehensive, and accessible guide to therapeutic MDMA use. It starts with a clear exposition on the science of trauma and healing, articulating a proposed mechanism by which MDMA therapy most likely achieves its effectiveness. It continues on to a thorough discussion of the practice of MDMA therapy, covering safety, dosage, what to expect physically and psychologically, and the role of clinical support. This includes discussion of complicating factors such as addiction, poly-drug use, and [contraindications](#). We have included detailed instructions on using MDMA to confront the painful and self-defeating feelings that underlie a wide range of implicit social biases. Finally, we include a discussion of therapies and therapeutic supports appropriate for augmenting MDMA therapy, as well as several appendices of supplementary resources to assist therapeutic MDMA users in getting the most out of their experience.

Many people are already doing professionally-guided or solo MDMA-therapy outside legal frameworks [140, 230]. The available information on the subject for these professionals, their clients, and DIY’ers is usually poor quality, locked behind expensive training programs, or

both. Often the institutions providing training advocate for a mix of evidence based and non-evidence based practices, which requires that individuals who wish to take an evidence based approach must do extensive research on their own. Our manual will provide a much-needed source of high-quality, accessible information on this subject. This can increase the accessibility and quality of MDMA-therapy and decrease its risks.

1.5 Summary for Mental Health Professionals

We have noticed many MDMA-therapy clients have questions, feel distressed, or are confused about parts of their professionally-guided MDMA-therapy sessions. We hope to remedy this by providing better information to therapists, guides, and clients.

MDMA adds a source of intense safety, compassion, and connection to a therapeutic session without the strong loss of self, hallucinations, or [traumatizing](#) experiences that LSD, DMT, or mushrooms can sometimes create. These emotional states make the engagement and unlearning of maladaptive patterns easier and more productive. MDMA's properties often makes therapeutic progress simpler than traditional psychotherapy; people are often able to make major therapeutic progress when all they do is 1) use the medicine in a relatively safe environment and 2) have some type of emotional (not just intellectual) engagement with maladaptive thought patterns or trauma responses. A therapeutic framework or highly attuned therapist often is not necessary. That being said, a structured and safe container (skilled, attuned, and ethical therapist or guide; prep and followup sessions) definitely increase the chances of benefit and reduce risk. MDMA's capacity for powerful and rapid therapeutic progress is also associated with a capacity for intense [destabilization](#) in those with severe complex trauma.

MDMA broadens the [window of tolerance](#), such that some degree of panic, [resistance](#), or [dissociation](#) is not a barrier to effective unlearning of maladaptive patterns during the session. Higher degrees of panic, resistance, or dissociation may still pose difficulty [243].

MDMA has a few serious medical and drug [contraindications](#), and additional caution and support is warranted in clients with dangerous or difficult to manage symptoms such as a history of psychosis, mania, suicidal ideation, and possibly severe lack of impulse control. Other than that it is generally safe and non-addictive in therapeutic contexts. See Section 3.1 for more information.

We think the following are highly important for a practitioner to be proficient in:

- Identifying and working with dissociation. See Sections 2.2 and 3.5.
- Identifying destabilization and helping their client manage it. See Sections 2.4 and 4.9.
- Maintaining especially high ethical boundaries and practices because idealizing transference may be intense. See Section 3.3. A number of licensed therapists and underground [psychedelic](#) guides have been in the news for taking advantage of their clients [221].

Recommended Reading Material

- *The Secrets of Supershrinks: Pathways to Clinical Excellence* This article explores the concept of "supershrinks" - therapists who consistently achieve superior outcomes regardless of their theoretical orientation or specific techniques [208]. The authors argue that exceptional performance in therapy, as in other fields, is primarily the result of deliberate practice and ongoing feedback rather than innate talent or experience alone. They propose a three-part formula for improving therapeutic effectiveness: determining one's baseline of effectiveness, engaging in deliberate practice, and consistently seeking and incorporating client feedback. By tracking outcomes, comparing performance to national norms, and actively working to improve skills through targeted practice and reflection, the authors suggest that all therapists can significantly enhance their effectiveness and client outcomes.
- *Unlocking the Emotional Brain, Eliminating Symptoms at their Roots Using Memory Reconsolidation* This book may have popularized the connection between [prediction error](#), memory reconsolidation, and therapeutic improvement. We think it is so useful that it should be required reading for all mental health professionals. Ecker [84] provides an important complementary resource addressing common misunderstandings and clarifies some fundamental mechanisms.
- *Fear and the [defense cascade](#): clinical implications and management* This paper lays out an integrated biological framework for dissociation, [fight-or-flight](#), and threat-induced alertness/tenseness. As noted in the paper, the clinical interventions section is speculative and we have low confidence in its theoretical correctness.

Chapter 2

**The Science of Trauma, Mental Illness, and Healing

2.1 Our Assumptions and the State of Mental Health Science

Robust scientific models are, as the pseudonymous blogger duo ¹ Slime Mold Time Mold [281] (one of whom is a cognitive scientist and statistician) state, is “a proposal for a set of entities, their features, and the rules by which they interact, that gives rise to the phenomena we observe.” They also make a wide variety of accurate [predictions](#) in the area of their relevance. Physics represents an exceptionally high degree of alignment to this standard; it has such a complete model of atoms that their properties can be predicted to many decimal points of precision. It also has a highly detailed and precise list of the entities involved (neutrons, protons, electrons, strong force, weak force, electromagnetic force) and the rules by which they interact. Few fields can match that level of completeness. In comparison, the political scientist Brian Klaas argues on their blog that the social sciences (psychology in our case) mostly use models that occasionally make good predictions in a narrow area, but rarely over a wide area [161]. Slime Mold Time Mold [281] further points out that psychological models don’t have convincing lists of well-defined parts and mechanisms and generally have no plausible connection to what neurons are doing in the brain. Working with these epistemically ungrounded abstractions is often a necessary first step to figuring out the set of mechanistic rules that govern the system one is investigating. However, a great number of these abstractions turn out to be false. That’s ok in the process of science, but, in our opinion, these provisional models have taken on a great deal of undeserved prominence in popular culture and clinical practice. These problems aren’t limited to the social sciences either. The neuroscientist Erik Hoel synthesizes a variety of papers in their blog to argue that even neuroscience is beset by severe systemic problems [141].

As Hoel [141] argues, neuroscience has no conclusively accepted overarching model (Pre-

¹The next two paragraphs largely rely on blog posts by several scientists. This is not traditionally-citable material, but we felt 1) this discussion is important to set the stage for the rest of the book, 2), these posts contain unusually high quality material by practicing scientists, and 3) we don’t have the capacity to sufficiently learn and synthesize this area of knowledge ourselves.

dictive processing is a compelling candidate and is the model we use [54].) of brain function. Because of this, most of the existing models of mental illness or psychiatric drug effects are incomplete, incorrect, or nonexistent. Mental illness is typically diagnosed according to somewhat arbitrary clusters of symptoms [21]. Mechanisms of action for psychiatric drugs, even when they have been rigorously shown to be helpful (though many either haven't been evaluated for long term efficacy and risk [175]), are typically only known as far as: drug -> specific effects on neurotransmitters -> ??? (part of the missing overarching model) -> observed changes in behavior/mood/etc. It is often tempting to say a drug works because of the "known effects on neurotransmitters" when the "???" may be just as, or more important. When a high quality (pre-registered, active-placebo-controlled, unblinding and expectancy effects measured and adjusted for, independent data analysis, unbiased staff, open data and code, multi-site, etc.) clinical trial does find an effect, that effect is statistical. It shows that the intervention causes some effect in the average person. It doesn't show the full chain of causation. Additional experiments are often needed to figure out the intermediate steps. We hope to sidestep some of these problems by basing this book on the [schemas](#)/predictive-processing and [defense cascade](#) models of mental illness that do have mechanistic explanations. These models don't seem to have percolated very far out of research labs into the world of clinical practice yet, though there are some exceptions.

In conclusion, we suggest taking any model (including ours, almost everything from psychology, much of neuroscience, most of psychiatry, and especially any pop-neuroscience) related to brain function or mental health with a large grain of salt unless there is "a set of entities, their features, and the rules by which they interact, that gives rise to the phenomena we observe [281]." As far as we are aware, a vanishingly-small number of mental illness models, and hardly anything in the field of psychology (See the psychologist Adam Mastroianni's blog post Mastroianni [197]) meet those criteria.

Our Core Assumptions

The following assumptions are the foundation of this book. Note that we don't have the deep subject matter expertise to really evaluate the mechanism-of-action of any of these phenomena. We primarily rely on other researchers' summaries.

- The predictive processing framework largely explains mental illness. Emotional learnings/schemas/priors explain the psychological part of mental illness, but not its genetic or physiological influences (Aizenbud et al. [5], A. Clark [54], J. E. Clark et al. [56], Ecker et al. [85], and Lane et al. [171]). - medium/high. Predictive processing is widely (though not universally) supported in neuroscience, has detailed mechanistic explanations for its functions (though some of them have not yet been experimentally investigated), and seems to neatly explain a wide variety of phenomena.
- Memory [reconsolidation](#) permanently unlearns maladaptive schemas (Ecker et al. [85], Elsey et al. [88], and Lane et al. [171]), though not the mechanism of all effective mental health therapy. Certainty - medium/high. Studies have established the protein-synthesis mechanism of memory reconsolidation in a variety of animals. Those experiments are not possible in humans because they are hazardous, but human studies have

verified many of the purported behavioral signs of reconsolidation. Controversy remains over exactly what conditions facilitate reconsolidation, what types of memory it can change, and some inconsistent experimental results. It also can't be ruled out that therapy facilitates a separate phenomena who's nuances appear similar to reconsolidation. Elsey et al. [88] conclude: "Nevertheless, we would argue that reconsolidation has provided a framework within which a range of new experimental manipulations and clinical interventions have been formulated and tested. Such investigations have already produced surprising and clinically relevant findings. We are not aware of any a priori hypotheses, besides reconsolidation, that would have predicted such results..."

- MDMA facilitates memory reconsolidation (or at least some phenomena that operates in roughly the same way and produces the same outcome) when used appropriately. Certainty - medium/high. MDMA-facilitated reconsolidation remains experimentally unverified. However, MDMA's effects of safety and empathy naturally decrease [avoidance](#) and facilitate staying present (requirements for reconsolidation [85]) with difficult schemas. Observations (summarized by A. A. Feduccia and M. C. Mithoefer [104], and additionally our own observations of trip reports) of post-session reports and MG's personal experience frequently match up with the signs (emotional non-reactivation, symptom cessation, and effortless permanence [85]) of a successfully reconsolidated schema. MG's personal experience and our observation of trip reports also indicate that once a maladaptive schema is emotionally activated and non-avoidance is practiced, MDMA pregnantly dissolves it without any further effort. It remains unknown what particular source(s) of information provide the [mismatch](#), or by what, if any, mechanisms MDMA facilitates reconsolidation other than safety and empathy.
- The section of the autonomic nervous system called the defense cascade explains the symptoms but not causes of anxiety, panic, and [dissociation](#) (Kozłowska et al. [166]). Certainty - high. To our non-expert eye the general principals of the defense activation seem well-established, non-controversial, and somewhat mechanistic.
- Acute physical injury from MDMA is almost always caused by mixing it with dangerous activities, certain other drugs, or certain medical conditions (Wolfgang et al. [322]). Certainty - high. The primary causes of injury seem well-understood and there haven't been any significant reported adverse effects in trials, where dangerous activity and drug interactions are absent, and participants are screened for cardiovascular problems. There could be rare exceptions that are poorly understood.
- Limited MDMA use does not cause long-term physical problems when used in therapeutic contexts and known medical [contraindications](#) are screened for (D. Nutt et al. [223]). Certainty - medium. We're not aware of any trials investigating this. A panel of drug misuse experts judged that in recreational contexts (where mixing it with other drugs, dehydration, and hyponatremia are much more common than in therapeutic contexts), MDMA-use carries some risk of physical harm to the user, though far less than alcohol. We think a majority of that harm can be attributed to the known risk factors mentioned in Section 3.1. MDMA is also used far less in therapeutic contexts than in recreation.

- MDMA does not directly cause long-term post-session cognitive problems when used in limited therapeutic contexts (Passie [230] and Wolfgang et al. [322]). Certainty - medium/high. One well-done observational study of recreational use gave recreational users (who on average used far more MDMA than is typical in therapy) a battery of 15 neuropsychological tests [130]. The MAPS phase II clinical trials also tested gave participants a variety of cognitive tests pre- and post-MDMA [215]. Therapeutic surfacing of [traumatic](#) material may still occasionally cause dissociation or panic-induced cognitive impairment.
- Therapy-induced psychological [destabilization](#) explains the vast majority of adverse symptoms, is "part of the process" when managed well, and further reconsolidation resolves destabilization (Olthof et al. [226]). Certainty - medium. There are compelling complex-systems models of it, though we're not aware of any experimental validation of proposed mechanisms. A variety of research has shown that destabilization is associated with better long-term therapeutic outcomes. Clinical and personal experience support the observation that the changed schemas which emerge from the reconsolidation process are typically followed by restabilization and improved functioning. We think a large majority of adverse psychological effects of MDMA-therapy at least appear highly compatible with destabilization, though we can't rule out other mechanisms.

Major Unresolved Issues

- We are not clear why MDMA-therapy induces prediction error for some schemas but not others, and why the schemas it tends to reconsolidate are casually or therapeutically identifiable as "maladaptive." We also do not understand what exactly "maladaptive" means in this context. A process can only be adaptive or maladaptive in relation to a goal or optimization function. Predictive processing posits that the brain's fundamental optimization function is minimization of prediction error, but it remains to be seen which particular sources of prediction error that function contains in most people [54]. Some near-immutable intrinsic sources of prediction error for almost everyone may include hunger, thirst, pain, companionship, etc., and the future fulfillment of these ². We don't know if MDMA-therapy optimizes your schemas according to your existing set of fundamental errors, or to some MDMA-modified set.

In our experience, MDMA-therapy seems to produce, in the long-term, changes that both the individual and their community feel are healthy and good. In this book we use the terms "maladaptive" and "adaptive" casually in this sense.

- We don't know how much, and for whom, MDMA-therapy will be destabilizing, other than thinking that destabilization risk is associated with complex early-life trauma. We also don't know when more MDMA-therapy will reduce or increase existing destabilization. See [2.4](#) for more information.

²Most or all behavior is composed of schemas optimized for future fulfillment of some set of fundamental sources of prediction error.

- Not much is known about when MDMA-therapy will make dangerous symptoms like mania, psychosis, and suicidal ideation better or worse. See [3.1](#) for more information.

Reference Quality

We applied a variety of checks on the validity of our references while writing this book:

- Retractions and PubPeer comments: All references via Zotero. We still cite the retracted papers Jerome et al. [[151](#)] and A. A. Feduccia et al. [[103](#)]. We think the reasons for retraction, while significant, don't majorly impact the part of the papers we cite them for.
- Reproduction of experimental results by other labs: No systematic evaluation, though we have made changes to the book when we happen across published replication failures.
- Validity of statistical methods and data processing: No references (outside our scope of expertise).
- Informal qualitative analysis of experimental design: Most references. We highly preferred papers that randomized their participants, had high numbers of participants, controlled for certain confounding variables for non-randomized studies, were recent (experimental and statistical methods have improved over time), were reviews or meta-analyses (these provide more robust results than individual experiments), and had high citation count (a partial indication that a paper outside our scope of knowledge is well-respected). Not all references meet high standards for all of these criteria. We may still have included them if they were, in our judgement, particularly theoretically compelling or reasonable extrapolations of more established results. Note that there are many indicators of quality that we did not check but that are often important, such as effect size heterogeneity in meta-analyses, topic-specific study design nuances, statistical methods, data processing methods, publication bias, researcher bias, etc.
- Contradictory evidence: Only the 8 important assumptions listed above. We put significant, though non-systematic, work into looking for evidence that contradicts these assumptions.

2.2 Defense Cascade

The Autonomic Nervous System governs a wide variety of involuntary bodily functions, such as heart rate and digestion [[166](#)]. In one of its roles, it activates a defense cascade—a sequence of responses—to shield us from threats. Increasing levels of perceived threat activate these responses, though the order of activation depends on individual variability and experience. Additionally, activation is proportional to our estimation of the threat and our ability to handle it. Children activate easily because the threshold of what constitutes a threat to their life is much lower than it is for healthy adults. Lack of parental support, attention,

or attunement (see Appendix C) can be life-threatening for children. Here is the defense cascade:

- **Arousal** The most common initial reaction to a potential threat. Think of how a deer becomes alert when they see something moving far away. Vigilance, muscle tension, respiratory rate, and heart rate all somewhat increase, allowing us to quickly assess and respond to possible dangers.
- **Fight-or-Flight** When an imminent danger is identified, like when a deer notices a wolf nearby or chasing them, this response prepares the body to immediately either confront (fight) or escape (flight) the threat. The adaptations of the arousal stage intensify and are augmented by an adrenaline surge, further suppression of pain, and an urge to fight or run.
- **Freeze** When the danger is imminent, but you might yet go unnoticed, the freeze response temporarily pauses a fight-or-flight response. If the predator notices you, freezing can quickly revert to fight-or-flight. While most physiological responses from fight-or-flight remain, opioids cause the muscles to become immobilized and heart rate decreases.
- **Tonic/Collapsed Immobility (Dissociation)** Tonic immobility (playing dead) may dissuade a predator from eating you when you have been caught. Fight-or-flight responses are deactivated, the body is partially-to-fully paralyzed, and the brain produces opioids which numb and disconnect you from reality. Muscles remain tense in case the predator gets distracted, and you have to run or fight again. This state may transition to collapsed immobility (fainting; muscle tension and consciousness partially to fully lost) when the threat further increases.
- **Quiescent Immobility** Tonic/Collapsed Immobility may extend into a lethargic rest and recuperation phase after the threat has gone. Occasionally, this may persist beyond its period of usefulness and become maladaptive.

The defense cascade originally evolved to activate during immediate physical threats like predation, but can also be activated by a wide range of stimuli (sounds, thoughts, places, etc.) associated with past threats. These associative activations are ideally adaptive; defense cascade activation upon sight of a wolf coming in the distance will give you more time to run than if activation occurs only after the wolf has bitten you. Unfortunately, associative activations can also be maladaptive. Think of the soldier who goes into fight mode in response to loud noises even after the war is over. Maladaptive defense cascade activation may be called PTSD (Post [Traumatic](#) Stress Disorder) for fight-or-flight responses, anxiety for arousal responses, or dissociative disorders for immobility responses. As described in the next two sections, MDMA-therapy can unlearn maladaptive associations between stimulus and activation.

Note that while others have used the term dissociation for a variety of phenomena, in this book we strictly define dissociation as the production and effects of endogenous (self-produced) opioids [166]. The specific effects vary depending on what type of opioids

(μ -opioids or κ -opioids) and other neurotransmitters are being produced, but generally include emotional numbing and detachment [166, 172]. We suspect there are opioid-mediated dissociative states that don't neatly fit into the defense cascade model. Some individuals ("... feel sober, or bored or sleepy as if they could get up and go about their day.") during MDMA sessions where the individual can presumably move and think fairly well, but remains emotionally numbed [245]. While we can't be sure that this phenomena is always opioid-mediated, we think it often is because emotional numbing is a known effect of opioids [172] and we aren't aware of any other mechanism that would cause such a degree of numbing as to make an MDMA trip feel boring.

Refer to Table 2.1 for a thorough comparison of the signs of intensified arousal and dissociation.

Table 2.1: Comparison of Hyperarousal [intensified arousal] and Dissociation Signs. Britton [40] compiled this from Ogden et al. [225], Magyari [191], and Treleaven [304]. Reprinted with permission.

Signs of Hyperarousal	Signs of Dissociation
Body/Somatic <ul style="list-style-type: none"> • Agitation, difficulty relaxing • Psychomotor hyperactivity • Tingling • Twitching • Hyperventilation, difficulty breathing • Exaggerated startle • Increased heart rate • Hot flashes, flushing • Sweating • Cold hands + feet • Muscle tension • Chronic pain • Insomnia 	Body/Somatic <ul style="list-style-type: none"> • Flaccid muscle tone • Extremely still (frozen) • Pale skin tone • Fixed gaze ("thousand yard stare"), glassy eyes

2.3 Trauma and its Effects

Our brains are fundamentally learning organs [54]. They continually build and run [prediction](#) and response models (formally called predictive processing) of the world, other people, our bodies, and our own mind for the purpose of fulfilling our innate needs for bodily integrity, community, health, reproduction, etc. Typically, we predict and respond to threats in an appropriate and unproblematic manner. We don't usually ruminate about falling off cliffs until we are near a cliff edge. Then the closer to the edge we go the more alert and cautious we become. This alertness or fear is not due to [trauma](#) because the response is situationally appropriate. However, not all responses are situationally appropriate. The brain's learning process doesn't necessarily build *true* models of the world, it builds models (an individual model is called a [schema](#)) that are *true enough* (heuristic) to work mostly-well in the contexts they develop in. These heuristics sometimes don't work very well outside of the context in which they form (Think of the soldier who goes into fight mode in response to loud noises even after the war is over.). We might describe trauma as events that create heuristics

that impair functioning in regular life. Lane et al. [171] describes traumas as distressing events or chronic conditions that overwhelm our ability to cope, where our ability to cope depends on our capabilities and resources. Standing near cliffs is not typically traumatic because the situation is under our control and we manage the situation to avoid overwhelm. If nothing surprising or threatening occurs, our predictions of what happens around cliffs doesn't change much. Conversely, threatening situations outside of our control create strong signals for updating our predictive model because your survival may depend on avoiding or managing that situation in the future. Maybe someone attacks you near the cliff edge and you almost fall off. Your brain may learn that cliffs (or the combination of cliffs and other people, or the combination of cliffs and just that particular person) are much more dangerous than you previously thought. You may feel alertness or fear from much farther away from the edge than you did before. If the attack was overwhelming enough you may learn that everything about cliffs is dangerous, even the thought of them or pictures of them. We think "high caution around that particular person" or "that person is dangerous and unpredictable" is likely the adaptive response in this scenario. Unfortunately the other responses, such as fear at the thought of cliffs, sometimes occur and can cause problems for you or others. Or instead of learning a somewhat helpful but not very accurate heuristic, you may learn a very accurate heuristic that only becomes a problem when your environment changes but the heuristic doesn't. These are the types of responses that we call maladaptive schemas and focus on throughout this book.

Here's another example of a schema that became maladaptive:

- Situation: As a young child, Amy was frequently ridiculed by her peers whenever she spoke up in class or shared her opinions.
- Initial Schema: "If I voice my opinions or stand out, I will be ridiculed."
- Resulting Behaviors and Beliefs: Amy grows up avoiding speaking in group settings and tends to keep her thoughts to herself. She might decline leadership positions or avoid roles where she'd be in the spotlight. In discussions, even if she disagrees or has a valuable perspective, she might not voice it. Amy might believe she's not as smart or valuable as others, even if evidence from later in life suggests otherwise.

This schema may operate either in the background or in explicit awareness, guiding Amy's behaviors and beliefs. If she is consciously aware of it she may or may not realize that this pattern is maladaptive.

Common traumas include:

- Different forms of unintentional or occasionally intentional neglect or abuse.
- Lack of emotional attunement from parents [43].
- Disasters, accidents, assault, or war
- Chronic poverty, dehumanization, or dysfunctional social-cultural systems [253]
- Loss of health, home, family, or culture

- A wide variety of other difficult situations

Some of these are single events, where the resulting schema is relatively simple. Someone attacked by a dog as a child may learn an intense fear of all dogs. Many traumas, especially chronic ones experienced during childhood, create complex networks of maladaptive schemas around things like your sense of self, relationships, your own body, etc. These are termed complex post traumatic stress disorder or [attachment disorders](#). They are often disabling because the schemas are intense and are activated by a wide variety of stimuli or a few particularly pervasive stimuli.

Mentally healthy adults with sufficient resources are resilient to most traumas and usually develop appropriate and healthy schemas to manage those situations in the future [35]. After the threat passes they may have a temporary period of anxiety about the experience called an acute stress reaction, but this typically dissipates within a few days of the event [135]. However, a variety of risk factors reduce the capacity to bounce back and form healthy schemas for that situation. Post-trauma factors for children, adolescents, and presumably also adults to a large degree, include blaming others, thought suppression, distraction, low social support, social withdrawal, poor family functioning, and parental psychological problems [305]. [293] also found that female gender (this may function differently in different cultures), unemployment, and low education are risk factors for adults. Resilience to trauma is complex [35], but we speculate that many of those items are risk factors because they are generally situations of broad resource (emotional, physical, social) insecurity, and are an additional "attractor" toward overly-general high-threat predictions (e.g. "I'm in danger everywhere"). The risk factors may also reduce circumstances that promote nuance (e.g. "My friendships remind me that I'm safe in many circumstances" or "I am already emotionally secure") or may directly inhibit [reconsolidation](#) (e.g. thought suppression). Note that while these factors may provide some prediction of resilience on a population level for certain situations, they might not be very predictive for any specific individual in any particular situation [36].

Our potentially maladaptive schemas usually update when our ability to handle adversity increases (like when we become adults and no longer rely on them for all our needs) or when the original difficulty ends. As further discussed in the following section, the updating process is initiated by "prediction error [85]." Prediction Error is a *consciously (though not necessarily explicitly recognized) experienced contradiction* between the original prediction (e.g. "broccoli tastes bad" experienced as a child eating mushy broccoli) and a new experience (e.g. "broccoli can taste good" experienced later an adult eating properly-cooked and seasoned broccoli). That prediction error updates your schema with the new information. This is a fundamental process enabling adaption to new situations, but a few things can inhibit this updating process by preventing this conscious contradiction, causing our schemas to keep operating in older, less adaptive ways:

- **Avoidance:** Anything that inhibits consciously experienced contradiction, like drinking alcohol when distressed, inability to tolerate uncomfortable emotions, possibly [Alexithymia](#), escapist habits, addictions, fear that updating a schema will make you vulnerable in some way, denial, projection, rationalization, etc. There is such a thing as healthy avoidance, which is temporary and helps you cope in non-destructive ways until you have the space to process.

- **Lack of Resources or Skills:** Not having a quiet moment or space to investigate and feel your emotions. Being unsure about the reasons for your reactions or how to handle them. Or you may not have skill in noticing and labeling feelings, sometimes called Alexithymia. Making schemas explicit, like with labeling, can aid the brain's built in contradiction-detection processes.
- **Fight-or-Flight or Dissociation:** These [defense cascade](#) states are strong enough to frequently inhibit prediction error [\[245\]](#).
- **Schemas May Just be Hard to Update in General:** All complex decision systems, such as the brain, must trade off between multiple goals. The psychiatrist Scott Alexander speculates in a blog post that the brain must trade off between two failure modes (these failure modes are well-established in artificial neural networks): over-generalization and over-specificity [\[10\]](#). Say that Alice was mean to you one time. An overgeneralized prediction may be that all people are mean all of the time. An over-specific prediction may be that Alice is only mean on Mondays, while wearing a blue shirt, when it is sunny out. Neither of these predictions are useful or correct; the correct prediction might be "sometimes people have bad days and take it out on others." Learning the correct prediction is difficult, and the brain must often make hasty guesses because learning a prediction too slowly can be risky in threatening situations. All of this possibly results in a messy system that sometimes generates overly-strong and durable predictions that require unusual circumstances to contradict.

When these continually inhibit prediction error for a maladaptive schema, the schema becomes stuck in its maladaptive configuration, replaying and creating problems [\[85, 242\]](#).

Schemas are not just simple stimuli-response pairs. In the model of Lane et al. [\[171\]](#) they have three components that we may be more or less explicitly aware of:

- Emotional responses like fear, anger, or love
- Beliefs like "my partner loves me" or "dogs are unpredictable and dangerous"
- Episodic memories (detailed memories of how specific events unfolded)

Schemas may not contain a clear episodic memory if you were too young to form long-term episodic memories that persist into adulthood. Though the reasons are unclear to us, many people also seem to forget experiences of childhood abuse. These memories can sometimes be later remembered (such as during non-directive therapy) and corroborated. We recommend The Psychedelics and Recovered Memories Project [\[301\]](#) for a nuanced guide on [psychedelics](#) and recovered memories. Schemas caused by such events can be confusing compared to schemas we clearly see a cause for.

The framework we just laid out is accurate but doesn't capture the full complexity of many mental illnesses. Maladaptive schemas and the defense cascade states they activate play a large role in the large majority of mental illnesses, unhelpful reactions, and emotional problems. However, the personal circumstances leading to the learning of particular schemas and mental illnesses are only part of the story. The prevailing model in the field is called the [biopsychosocial](#) model [\[91\]](#). It describes how many mental illness arise through complex

interactions of biology (genetics, medical history), psychology (trauma, schemas), and social context (social models of how you should respond to trauma, support networks, living situation). Hayes and L. A. Andrews [137] summarizes a variety of research (citations 13, 17-26 in the original) on this complex-systems modeling of mental illness:

...a dynamic system [a person in this case] is a set of interconnected elements that evolve over time and self-organize into higher-order functional units, called attractor states [stable patterns of behavior, beliefs, emotions], that are preferred and govern system behavior. Self-organization is the process by which lower-order processes [individual schemas, defense cascade activations, elements of life circumstances, gene variants, etc.] interact and higher-order patterns emerge and then influence the lower-order processes in a top-down manner. Attractor states constrain system behavior such that it tends to be “pulled” back to these states when perturbed. An adaptive [healthy] system is flexible as conditions change, but also able to maintain functional integrity in the face of perturbation. A system that has multiple functional patterns (known as multistability) can flexibly switch between patterns to meet the demands of internal and external challenges.

Attractors that are well-established have strongly interconnected elements, with reinforcing and inhibiting feedback loops that can increase or decrease the probability of activation over time and contexts. When attractor patterns are entrenched, they become rigid and relatively insensitive to challenges or new information [as in most mental illness]. Significant disturbance [like the gradual dissolution of maladaptive schemas] or strong jolts are therefore required to disrupt these patterns. Less developed or [destabilized](#) attractors have a weaker hold, allowing the system to more easily switch to alternative states [like high functionality and healthy emotions].

This book primarily focuses on the "psycho" part of "biopsychosocial," with secondary focus on the "social."

About 10% of the population might meet the somewhat arbitrary criteria for mental illness at any given time [323], but we suspect almost everyone has some amount of maladaptive schemas that negatively effect them and those around them. We think these schemas may push us to overreact, deny the truth, misjudge important trade-offs, say hurtful things, etc. We may seek out the connection and safety we desperately need in dysfunctional ways [43]. Or we may get too distracted by our distress to pay attention to the needs of those we love. The stress of chronically activated distressing feelings or chronic defense cascade activation also significantly increases risk for a wide variety of physical diseases and problems as discussed in Section 2.5.

For more information we highly recommend *Unlocking the Emotional Brain: Memory Reconsolidation and the Psychotherapy of Transformational Change* by Bruce Ecker, Robin Ticic, and Laurel Hulley as essential reading for all mental health professionals and anyone else interested in the topic [85]. If you're interested in the general theory of predictions in the brain, we recommend two definitive books by Andy Clark, Ph.D. on predictive processing. *Surfing uncertainty: Prediction, action, and the embodied mind* is the more technical, though not mathematical, of the two books [54]. S. Alexander [8] provides a good accessible summary

of it. *The experience machine: How our minds predict and shape reality* is the less-technical mass-market version [55].

2.4 Mechanism of Healing

As discussed in the previous section, a consciously experienced contradiction between an old [schema](#) and a new experience or existing knowledge creates [prediction](#) error [85]. Prediction error triggers an updating process called memory reconsolidation. When schemas are first created, they are *consolidated*. After that, when a consciously experienced contradiction creates prediction error for that schema, the schema enters a state of plasticity where it can be changed. Maintaining that experience of contradiction over a period of time will then gradually update the schema to account for the contradiction. About 5 hours (in animal models) after the initial prediction error, the memory is *re-consolidated*, re-entering a stable state where it can no longer be changed without another consciously experienced contradiction. Throughout this book for convenience we will use "reconsolidate" in a slightly different way to denote the entire process of schema destabilization, updating, and restabilization.

Thus, durable long-term unlearning of stuck or maladaptive schemas is a process of memory reconsolidation. Mismatches can come from a variety of sources: feelings of safety and connection from an attuned therapist, a second activated memory, secure relationships, everyday life, and a wide variety of other experiences and knowledge. We've observed that in practice, MDMA seems to facilitate or provide effective mismatches for most, if not all maladaptive schemas, in contrast to traditional psychotherapy, where specific mismatches must be found for each schema. Carhart-Harris and Friston [48] theorizes that [psychedelics](#) potentially relax all high-level (e.g. "I am bad," as opposed to low-level schemas that control, say body temperature, which remain largely unaltered) schemas, thus making all types of contradictory information more liable to inducing prediction error and reconsolidation of maladaptive schemas. We don't know exactly what type of contradictory information you might encounter in any particular scenario, but we have a few somewhat overlapping hypotheses:

- The present moment, which is in all likelihood safe, thus contradicting predictions of danger, which most or all maladaptive schemas may be to some extent.
- Connection might contradict all schemas fundamentally about some sort of disconnection from life, safety, love, etc.
- [Non-dual](#) awareness, which might be a form of deep, inviolable connection.
- Interoception [48]
- Other schemas you already have, as is often used in therapy [85].

It could be that multiple of these occur at the same or different times throughout one or more sessions. In all cases, MDMA's safety and empathy also make it easier to stay present with the emotional activation of your highly distressing schemas, a requirement for reconsolidation.

We posit that there are at least three practical ways of using MDMA to aid memory reconsolidation, though in reality, more than one of these may happen during any given MDMA-therapy session:

- Using the mismatch facilitated by MDMA, whatever its exact source, to reconsolidate a maladaptive schema during the session by activating and staying present with the schema. This could be as simple as staying present with some fear-based schema, then noticing it dissipate over a span of minutes to 10's of minutes.
- Using the feelings of safety from MDMA to make your implicit ("I have this maladaptive behavior but don't understand why and don't know what the schema is") schemas explicit ("I do the maladaptive behavior because my schema says...."). Explicit schemas are often easier to mismatch through regular therapy after the session because. Absent extraordinary states of mind, finding a mismatch typically requires knowing what the schema is [85].
- MDMA may show you new knowledge (e.g. "I have an inner well of inviolable safety") that you can then use outside of the session as a mismatch for a wide variety of maladaptive schemas. We're aware of a few anecdotes of this occurring.

These processes are conceptually quite simple, but practical use is usually more complex. People's target schemas are often very intense and may require multiple sessions to fully reconsolidate [211], or they may have multiple maladaptive schemas they wish to work on. Additionally, individuals usually only have a partial understanding of the schemas causing their problems, so they often end up needing to work on schemas they weren't initially aware of.

We think another complexity, destabilization (psychological turbulence), is commonly a challenging part of MDMA-therapy. You can think of it as standing up. Sitting and standing are both stable positions. The transition positions between the two are unstable, but must be passed through if you want to walk anywhere [226]. Therapeutic destabilization is associated with better outcomes later in therapy, however it can negatively impact your life if it is severe enough and not managed well. We think the following is a likely schema-based description of destabilization: Initially, multiple schemas and [defense cascade](#) states may work together to create a relatively stable but unhealthy pattern of behavior and emotions. Unlearning all or most of the schemas in that pattern may be necessary to reach a healthier pattern, but that can't be done all at once. Starting the reconsolidation process triggers an intermediary period where some of the schemas still exist but no longer form as stable of a pattern. We suspect some of them may react to the new state by strengthening and possibly activating defense cascade states. "Protector backlash" from the Internal Family Systems framework may describe a similar phenomena [269]. We are not aware of any papers demonstrating this, but, based on a large number of anecdotal reports from reddit.com/r/mdmathrapy, we think it's highly likely that psychedelic therapy tends to produce stronger destabilization (and more rapid therapeutic progress) than traditional psychotherapy. See Section 3.3 for tips on assessing this risk. We recommend Hayes and L. A. Andrews [137] for a more thorough theoretical explanation of destabilization.

Here are some hypothetical examples of destabilization: Occasionally one maladaptive schema may provide some valuable functionality in your life that your other maladaptive

schemas would otherwise inhibit. For example, you might have two schemas: 1) "nothing matters" (disincentivizes doing chores) and 2) "I have to do chores because I'm responsible for everything all the time" (incentivizes doing chores). Schema 2 may help you do chores even when schema 1 would otherwise prevent it. MDMA-therapy could possibly reconsolidate schema 2 before schema 1, leaving you unable to do the chores until you also reconsolidate schema 1. This is a temporary decrease in function during the process of therapy. Furthermore, for those with complex networks of maladaptive schemas, the state of not doing chores could conceivably exacerbate a third schema that is something like "I deserve to die if I'm not being useful." While that schema may have been influencing your feelings and behavior all along, if you had not ever felt useless before (as you do now when not doing chores) then it may have not ever escalated to suicidal ideation until now when you can't do the chores. We hope these illustrate that convoluted chains of schemas and dysfunction are sometimes encountered in the reconsolidation process. In real life this can be considerably more complex and opaque.

Destabilization may also just consist of activating [previously-dissociated](#) or avoided memories. This may be overwhelming, or may activate debilitating defense cascade states.

Reconsolidation reduces the intensity of distressing feelings of a schema, but as previously discussed, schemas also contain abstract beliefs (e.g. "I am a bad person") [171]. As such, the reconsolidation process may produce changes in self-conception, alterations in your narrative surrounding the schema, shifts in associated beliefs or values, expansion of emotional perspectives, integration of previously separated aspects of the experience, or the development of greater cognitive flexibility in relation to the event. You may not even conceptualize the experience as activation and reconsolidation of a maladaptive schema.

Ecker et al. [85] describe the following signs of a completely reconsolidated schema:

A specific emotional reaction abruptly can no longer be reactivated by cues and triggers that formerly did so or by other stressful situations.

Symptoms of behavior, emotion, somatics, or thought that were expressions of that emotional reaction also disappear permanently.

Non-recurrence of the emotional reaction and symptoms continues effortlessly and without counteractive or preventive measures of any kind."

Reconsolidation is the core mechanism of unlearning maladaptive schemas, but it is not the only part of healing. Learning healthy habits and emotional skills may also critical. We discuss some relevant topics in different parts of this book.

Fear extinction is another strategy commonly used to deal with maladaptive schemas [85]. We mention it here only to discuss why we do not focus on using it. In fear extinction, one attempts to create a secondary schema that activates in response to the same stimuli that activate the maladaptive schema. Ideally, this secondary schema will preferentially activate instead of the maladaptive one. The process is time-intensive as it requires individually training the secondary schema for every stimuli you want it to activate for. It is also fragile because the maladaptive schema remains unaltered and will activate any time you encounter a stimuli you have not sufficiently trained the secondary schema for. As Doss et al. [79] states based on Dunsmoor et al. [82], "Extinction memory is characteristically weaker, more transient, and more contextually specific than the original fear memory, rendering conditioned fear susceptible to return under a variety of circumstances."

We highly recommend Sotala [285]. It describes the fundamental process of updating maladaptive schemas better than any other resource we are aware of, short of the book they are reviewing.

2.5 Efficacy of MDMA-Therapy

The MDMA phase 3 clinical trials (the final round of clinical trials that test efficacy and safety on a large sample size) reported that MDMA-assisted non-directive psychotherapy highly outperformed placebo-with-therapy treatments for PTSD, as Table 2.2 shows [211, 212]. Each subsequent dose (the trials included 3 doses) improved outcomes further, likely indicating further doses would further increase healing. The reported outcomes persisted when the data was reanalyzed by an independent, blinded programmer. Only 5% of participants in the MDMA groups discontinued treatment (half for reasons unrelated to the study), compared to 16% in the placebo groups. MDMA-therapy worked across severity of symptoms, presence of other mental illnesses, and history of ineffective treatment. The phase 2 long term follow-up study shows the effects are durable [151]. While rigorous and highly promising, these studies were organized by a single organization, and a different methodology may show different results. MDMA-therapy with therapists less familiar with MDMA may also be less effective. See Wolfgang et al. [322] for a more thorough discussion of efficacy.

Trials for all types of mental health interventions rarely control for expectancy, one type of placebo effect [148]. This results in much of the field using poor quality data that doesn't properly differentiate how much of the treatment effect is due to study bias vs. the intrinsic effects of the treatment itself. This most obviously affects trials where blinding is impossible, like psychotherapy and mindfulness. However, it also affects trials that do attempt blinding, but where the effect of the medicine is noticeable enough that the patients or providers unblind themselves. After un-blinding, the patient's and provider's expectations about whether the medication works then alters how much the treatment actually works, confounding the data. [Psychedelic-assisted-therapy](#) trials like the MDMA trials possibly have worse-than-typical unblinding (because the effects of the medicine can be so dramatic) and researcher bias compared to typical trials for psychiatric drugs [3]. We suggest van Elk and Fried [314] for a thorough discussion of these problems. We think MDMA-therapy is more effective than placebo due to 1) anecdotes of durable therapeutic improvement in situations where the user was intending a recreational, rather than therapeutic experience, but happened to activate some maladaptive [schemas](#), and 2) our observations of personal reports of MDMA-therapy outcomes consistently match up very well with the signs of successful [reconsolidation](#) listed by Ecker et al. [85].

Table 2.2: Mean (Own work derived from Fig. 3 in J. M. Mitchell et al. [211] and Fig. 3 in J. Mitchell et al. [212]) outcomes from the first and second phase 3 clinical trials (174 total participants). These numbers represent therapeutic progress related to the single [traumatic](#) event that participants chose as their therapeutic target. However, another measurement collected in the studies, the Sheehan Disability Scale, reported similarly large gains in total life-functionality independent of progress related to that single traumatic event. Those with multiple traumatic events or mental illnesses, as is common in early-life trauma, will need a longer time frame and number of sessions to reconsolidate all the schemas they want to address. "Clinically Meaningful Response", "Loss of Diagnosis", and "Remission" are labels applied to escalating degrees of improvement.

	MDMA w/ Therapy	Placebo w/ Therapy
No Response	13 %	35 %
Clinically Meaningful Response	87 %	65 %
Loss of Diagnosis	69 %	40 %
Remission	40 %	13 %

As previously mentioned, mental illness is a complex interaction of biology (genes and medical history), psychology (schemas, in our view), and social context [91]. How much role genes play in each specific mental illness is not settled, but it does appear to vary significantly [20]³. We think reconsolidation can likely resolve the "psycho" part of "[biopsychosocial](#) [48, 85]," which we suspect plays a significant part in the large majority of mental illness. How much this will resolve the symptoms of any individual's particular problem is unclear, but the above results for PTSD are extremely promising. Here is grab-bag list of information we are aware of for particular disorders (Take these with a grain of salt. None of these trials controlled for blinding or used active placebos.):

- ADHD is a heterogeneous collection of symptoms with multiple causes, not a single well-defined disorder [188]. Because of this, it is difficult to say whether some subtypes of ADHD might be schema-based and amenable to treatment with MDMA-therapy. The symptoms of certain types of [attachment disorders](#) (clearly schema-based in our opinion) also overlap with ADHD symptoms, making the two difficult to distinguish [111].
- MDMA-therapy cannot cure autism, which is almost entirely driven by genetics, but it can treat the anxieties that autistic people often have [68, 294].
- MDMA-therapy is effective for durably improving alexithymia (difficulty in identifying and describing emotions) and reconsolidating maladaptive schemas in the presence of strong alexithymia (often a barrier to reconsolidation) [312].

Determining to what degree any particular issue is caused (Either self-assessed or clinician-assessed.) by maladaptive schemas is frequently difficult, in no small part because the poor

³Some of the major genes involved in mental health may function by making individuals more generally sensitive to their environment such that in environments of adversity they function worse than average and are more susceptible to a variety of mental illnesses, but also function better than average in response to healthy environments and childhoods. [20].

state of current mental health practice and science. In the face of this uncertainty, trying MDMA-therapy may help if you meet the safety criteria (See Section 3.1). It offers some chance of addressing the problem if it is schema-based, and very low risk if you don't have any emotional issues, though we think [destabilization](#) is a significant risk if your problem is schema-based.

Many mental illness symptoms, such as mania and psychosis, are also activated or exacerbated by stress [307, 315]. Reconsolidation could potentially reduce these symptoms if your stress is significantly caused by maladaptive schemas.

2.6 Physiological Health Effects of Trauma

Certain types of [trauma](#), especially multiple severe traumas in childhood without a mediating [secure attachment](#) relationship, increase the risk for a wide variety of chronic health conditions [133]. This may occur either through harmful coping behavior [106] or chronic high stress causing problems with the hypothalamic-pituitary-adrenal axis [185] and immune system. Other mechanisms may exist too, and though we are not sure to what degree each particular problem is caused behavioral vs physiological mechanisms, it has been proven that these correlations exist outside of behavioral differences. Childhood traumas are robustly associated with an increased risk of cardiovascular problems (e.g. heart attack, stroke, ischemic heart disease), respiratory problems (e.g. asthma, bronchitis), gastrointestinal problems (e.g. hernia, spastic colitis), metabolic disorders (e.g. diabetes, obesity), neurological problems (e.g. headaches, migraines), musculoskeletal problems (e.g. arthritis, broken bones), ulcers, sexually transmitted diseases, cancer, and autoimmune disorders [146, 222, 320]. Conditions like fibromyalgia, functional dyspepsia, chronic fatigue syndrome, and irritable bowel syndrome are also significantly correlated with anxiety, depression, and childhood trauma history, can have a major negative impact on quality of life, and are notoriously difficult to obtain satisfying medical care for [115, 139, 277]. We have observed that, due to physician perceptions that the symptoms of some of these disorders are "vague" and "subjective," these conditions can be particularly subject to medical gaslighting, exacerbating ongoing stress for those who experience them. Dementia is also strongly associated with childhood trauma [273]. These are assuredly a limited subset of the full set of disorders associated with childhood trauma. We are not sure to what degree each particular disorder can be reversed by unlearning the underlying [schemas](#) and associated stress or behaviors, but there are many anecdotes of improvements to a variety of disorders following successful therapy [311]. We are hopeful that psychoneuroimmunology may be helpful in addressing this category of conditions, and we are excited to witness the next decades of research on the physiological impacts of trauma and mental illness.

For additional popular-press coverage of the physiological impacts of trauma and how to heal them, we strongly recommend *The Deepest Well* by Nadine Burke Harris [133].

Chapter 3

Preparation

3.1 **Safety and Challenges

MDMA-therapy is generally well-tolerated, but there are dangerous drug interactions, medical [contraindications](#), side effects, and psychological risks [322]. These risks are mostly well-understood. As detailed later, MDMA-related problems are caused by [247, 256, 322]:

- Prolonged, intense physical activity in high temperatures combined with dehydration. This may cause heat exhaustion or heat stroke. High water consumption not balanced with salt can also cause dangerously low sodium levels. Alcohol co-use strongly exacerbates the risk of these problems. Potentially deadly.
- Taking MAOIs (including ayahuasca) within 2 weeks of a session. Potentially deadly.
- Co-use with other psychiatric medications is unlikely to be dangerous, but may increase side effects or decrease the therapeutic effect.
- Co-use with amphetamines, stimulants, and opioids may be particularly risky.
- Liver or cardiovascular problems. Risk unclear.
- Exceedingly high doses. Risk unclear. A cautious upper bound may be 200mg.
- Extremely high lifetime use can cause heart problems. It could also conceivably cause other, poorly understood problems.
- Adulterated pills. This can be checked with test kits, though laboratory testing is much better. Risk unclear and varies by adulterant.
- Therapeutic [destabilization](#) is a common and healthy phase of therapy for those with severe [trauma](#). Unfortunately, the presence of a major risk factor for destabilization, severe early childhood trauma, is difficult to self-assess without (and sometimes even with) professional assistance. [Psychedelic-assisted](#) therapy speeds up both healing and destabilization. History of psychosis, mania, and suicidal ideation are strong indications to work with a highly skilled and trusted practitioner familiar with these

conditions. Destabilization is sometimes overwhelming and can cause major problems when poorly managed or entered into at an inappropriate moment in your life.

- Psychedelic experiences occasionally provoke destabilizing shifts to one’s sense of self or one’s beliefs about existence.

Putting this in perspective, one panel of drug-misuse experts estimated that, even in recreational contexts where users are likely not as cautious as they should be of risks, MDMA poses a significantly lower overall health risk than marijuana, and far less than alcohol [223]. However, we suspect that anyone undergoing MDMA therapy likely has a higher chance of therapeutic destabilization than the average recreational user.

Drug Interactions

If you regularly take another medication, we suggest consulting M. Liechti and Schmid [177] (more accessible) or Sarparast et al. [263] (more technical) for recommendations on whether you need to discontinue it for a period of time before your session. We don’t know enough to specifically recommend this resource, but one psychiatric pharmacist specializing in psychedelics offers consultations and drug-interaction resources [194]. If your medicine is essential for your health we strongly suggest consulting your doctor on how, and whether, you can safely pause it. They will likely not understand the effects of MDMA, so you may need to provide Sarparast et al. [263] to them. That paper discusses pharmacokinetics, metabolism, and various drug interactions. If your medication isn’t on one of these lists, you can’t access a doctor or pharmacist, and you can temporarily discontinue it with tolerable effects, discontinuing it for 5 drug half-lives (Each drug has a different half-life, which can be found on [DrugBank](#) under Pharmacology->Metabolism.) before the session and 2 days (5 MDMA half-lives) after the session would generally ensure that 98% of a drug has been excreted from your body [14, 70]. This does not account for health conditions that affect metabolism or other relevant processes. On rare occasions a drug’s relevant effects persist even after it has been totally eliminated from your body, as is the case with reuptake inhibitors and MAOIs.

- Taking MAOIs within two weeks of an MDMA session can cause a deadly effect known as serotonin syndrome [86, 195]. Notably, one component of ayahuasca is an MAOI [257]. Co-use with amphetamines, stimulants, and opioids can also produce serotonin syndrome [193]
- Reuptake inhibitor medications, including SSRIs, SNRIs, NRIs, and NDRI, highly inhibit the effects of MDMA [103]. Long term use of these medications causes this effect to persist long after medication discontinuation. Discontinuation 25 days before an MDMA session still reduces therapeutic efficacy of MDMA-therapy by about half. Further discontinuation may bring further benefits. Discontinuation typically requires multiple additional weeks of tapering to manage withdrawal.
- Combining MDMA with other prescription psychiatric drugs can cause a variety of changes to the intensity or duration of various effects [263]. No generally high-risk interactions, except for MAOIs, have yet been found. However, some may increase low-moderate-risk adverse effects or decrease the therapeutic effects of MDMA.

- The liver enzymes CYP2D6/COMT, CYP1A2, CYP2B6, CYP2C19, and CYP3A4 metabolize MDMA [72, 263]. Flockhard [109] maintains a list drugs that inhibit, enhance, or are metabolized by CYP enzymes. Drugs that enhance CYP enzymes may reduce the intensity and duration of MDMA effects. Combining large doses of drugs that are metabolized by CYP with MDMA may overload one of these metabolic pathways and potentially cause problems, though it's unclear which drugs and how much. Drugs that strongly inhibit these enzymes, such as ritonavir, may be dangerous to take with MDMA [263]. Again, the degree of danger is unclear and dependent on a drug's degree of inhibition and dose. Some inhibitors, like SSRI's, don't seem to cause dangerous effects (other than reduced therapeutic benefit) when combined with MDMA. The multiple enzymes provide some redundancy if one pathway is inhibited, making drugs that inhibit multiple enzymes particularly dangerous.
- Pills marketed as MDMA can contain harmful adulterants [261]. We suggest using test kits (lab testing like Kykeon Analytics [168] or Energy Control International [90] is better, though we have not vetted these particular services), such as DanceSafe's, to check for contaminants if there's any doubt about its quality [66].

Medical Contraindications

- MDMA, as a stimulant, increases blood pressure to 147/89 mmHg and heart rate to 92 b/min in the average user in therapeutic contexts [211]. Transient increases in systolic blood pressure to above 180 mmHg also occurred in 5% of users in one study [317]. This may be a risk for individuals with cardiovascular disease. Individuals with "...uncontrolled hypertension, history of arrhythmia, or marked baseline prolongation of QT and/or QTc interval" were excluded from clinical trials for this reason [212]. That may not be a complete list of cardiovascular conditions contraindicated for MDMA. It's unclear exactly how much of a risk these pose. A search of the FDA Adverse Event Reporting System found "A total of 17 unique cases were reviewed in this study. There were no reports where MDMA was taken as a single agent and ischemic, hypertensive, or arrhythmic AEs were reported. All cases included concomitant medications with known associated cardiac function abnormalities [192]."
- Extremely high lifetime MDMA use, possibly along with high use of other psychedelics, may cause valvular heart disease [80, 292]. In one observational study, 28% of chronic MDMA users showed signs of valvular heart disease (VHD) when evaluated with echocardiography, compared to 0% in a matched control group who reported no MDMA use [80]. The chronic users with clinically significant VHD self-reported a mean consumption of 943 MDMA tablets, while the chronic users without clinically significant VHD reported a mean consumption of 242 tablets. This may give a very rough indication of how much MDMA is needed to cause VHD.
- Some types of liver problems may inhibit metabolism of MDMA enough to cause problems. We suggest consulting a doctor.
- MDMA, like many medicines, may have uncommon, poorly understood side effects,

particularly after long-term high-frequency use, or in populations with certain genetic features or health problems. Long term (1 year) follow up has only been conducted with 103 individuals and no study can investigate all possible health effects [151].

- MDMA commonly causes mild hyponatremia (low plasma sodium concentration) in individuals who drink fluid (presumably unsalted, like plain water) during the session, though not in those who don't drink anything [22]. This was found in clinical settings where physical activity was low and temperature moderate. Hyponatremia can become severe if the individual sweats a lot and doesn't hydrate enough, or drinks large amounts of unsalted fluid, as sometimes occurs at dance parties [313]. Mild hyponatremia doesn't seem to be a significant problem for most people in typical therapeutic environments [211]. Dangerous heat illness can also occur if you sweat a lot and don't hydrate in a hot environment, as also sometimes occurs at dance parties [313]. Exercise increased caution if your body has severe problems regulating its temperature because MDMA raises body temperature by 0.2-0.8°C or 0.4-1.4°F [178]. Alcohol co-use also significantly exacerbates the risk of heat illness and hyponatremia [313].
- Planning careful or reduced movement during altered states of consciousness may be advisable if your body is prone to injury from otherwise typical human movement. A sitter, guide, or therapist could help you with this during the session, or you could put an obvious reminder sign in your field of view.
- Kangaslampi and Zijlmans [157] saw no obvious reasons why adolescent use would be risky. However, this assumption has not been tested in any trials. Developing individuals could react differently to MDMA than adults. These unknowns may have to be traded off against the fact that treating mental illness is also important, and MDMA-therapy shows promise for resolving "treatment-resistant" mental illness [211].

Psychological Risks

- Psychological destabilization (See Section 2.4) is a common occurrence in therapy [226]. It's associated with better outcomes later in therapy, but if it is intense enough and not managed well can interfere with your life. We are not aware of any papers demonstrating this, but we think it's likely (from anecdotal reports) that psychedelic therapy tends to produce stronger destabilization (and more rapid therapeutic progress) than traditional psychotherapy. See Section 3.3 for tips on assessing this risk.
- Psychotic episodes induced by therapeutic doses of MDMA without confounding factors are rare [17]. One participant out of 174 in the phase III clinical trials reported a psychotic episode (after the trial ended) even though participants with any known personal history of psychotic disorders were excluded from participation [212, 221, 282]. Those with family history were not excluded. Published case reports of psychosis following recreational MDMA-ingestion almost always involved confounding factors like co-use of other psychoactive drugs, lack of verification of MDMA ingestion, dehydration, extreme doses, or extreme frequency of use [201, 231, 310]. Even if the risk of

MDMA-induced psychosis is very low, the consequences of psychosis can be high. Because of this, we suggest that a personal history (or a family history for those with lower risk thresholds) of psychosis is a strong indication to work with a groups of professionals who thoroughly understand both psychosis and MDMA. One survey of experts in psychosis and psychedelics reported consensus on psychedelic therapy for psychosis being worth investigating, but that clients should have especially high in-session and post-session support [169]. We have personally heard of two cases of psychosis triggered by a high-dose psilocybin trip conducted the day after an MDMA-therapy session. This suggests a lack of adequate recuperation between sessions is a major risk factor.

- Possession of multiple doses may be risky for those with severely impaired impulse control if they see the medicine as an escape, an immediate drug-based solution that doesn't require any therapy component, or don't understand the need to recover between sessions. They may use too high of doses, use it too frequently, or use it in unsafe contexts.
- Altered states of consciousness can impair awareness and judgement. Avoid driving and other potentially risky activities on the same day as the session.
- MDMA therapy decreases suicidal ideation about as much as placebo with therapy, on average [211, 212]. However, averages mask the possibility that a small portion of individuals can get worse even while the majority improve. As with psychosis and mania, we think individuals with suicidal ideation should have especially high in-session and post-session support.
- Mania is a dangerous condition that could also conceivably be exacerbated through therapeutic destabilization, though we are not aware of any good data on actual risk. The exclusion criteria for the MDMA-therapy clinical trials may offer some preliminary guidelines: individuals with bipolar I were excluded but those with bipolar II were not [212]. One small, uncontrolled study with highly-motivated participants not currently in a manic or hypomanic state showed good efficacy and safety treating bipolar II with psilocybin and a high level of support [1]. We aren't sure how well that translates to MDMA-therapy. We think a personal history (or family history for those with lower risk tolerance) of problematic mania is a strong indication to work with a team of trusted professionals who understand both mania and MDMA. As with psychosis, we think individuals should have especially high in-session and post-session support.
- Complex or compelling distortions of external reality on MDMA are rare and correlated with high doses, but people more commonly have closed-eye visuals (possibly involving traumatic events they experienced) [179]. These visuals may be symbolic instead of a realistic reliving. Temporary and mild visual changes such as color and texture enhancement are common. Sometimes psychedelics, along with many other psychoactive drugs, trigger persistent visual distortions [9, 129]. When this causes significant distress or impairment it is called Hallucinogen Persisting Perceptual Disorder (HPPD). HPPD is strongly linked to pre-existing anxiety or [dissociation](#), and often improves as those are treated. HPPD from MDMA is unrecorded in clinical trials, but

some recreational users report it [183, 317]. One survey found that when people do report persistent visual or auditory distortions (from any psychedelic), 73% say "they [the symptoms] don't bother me at all", 24% "I'd rather not have them but I can live with them", 0% "they irritate me", and 1% "they drive me mad [49]."

Evans et al. [100] surveyed people who have experienced new, persistent negative symptoms after recreational, professional-therapeutic, and DIY-therapeutic psychedelic experiences. This data applies to all psychedelics, not just MDMA. Most symptoms dissipated with time, but 17% of respondents said theirs lasted more than 3 years. From most to least common, participants reported emotional (76%), self-perception (58%), cognitive (52%), social (52%), ontological (50%), spiritual (34%), perceptual (26%), and other (21%) difficulties. There is major uncertainty in how much these symptoms are:

- Surfacing of existing maladaptive [schemas](#) and subsequent [defense cascade](#) activation, a necessary and healthy part of the therapeutic process if managed well. You may have been avoiding these schemas until the session. *We think there is a high likelihood of this for MDMA therapy. It's conceivable that a highly skilled therapist could help you keep surfacing material to small, easily dealt with chunks, but psychedelic experiences are famously difficult to control.*
- Trauma from life impairment or destabilization due to poorly managed surfacing of maladaptive schemas and trauma. *This is possible, though the risk can be significantly reduced with expert guidance and high quality support.*
- Trauma from the psychedelic experience itself. *We think this usually results from large doses of hallucinogens, unsafe settings, and abusive or incompetent guides/therapists. We think traumatization risk is low for MDMA itself because of its deep feelings of safety and tendency toward low hallucinatory effect.*
- Difficult or destabilizing changes to your understanding of self, existence, or meaning. *MDMA might occasionally induce this [96].* See Section 4.2 for more information.
- Something else. We don't know if this exists, and if it does, what it is.

Even in this subgroup of people who experience extended difficulties in the previously mentioned study, 90% agreed with the statement "I believe that the insights and healings gained from psychedelics, when taken in a supportive setting, are worth the risks involved [100]."

However, it is possible that a population of psychedelic users who experience debilitating effects was missed due to sampling bias. A similar study using a different set of categories found that those with adverse symptoms from psychedelics had: sense of social disconnection (72% of study participants who reported adverse symptoms), anxiety and panic attacks (68%), existential struggle (65%), feelings of depression (61%), derealization (55%), diminished self-esteem (50%), depersonalization (37%), sleep problems or nightmares (35%), difficulty with thinking clearly (33%), paranoia (21%), visual hallucinations/disturbance (21%) [250].

Other Common Concerns

- **Discomfort with Drugs** While MDMA-therapy is not for everyone, healing can happen even when discomfort is present during a session because MDMA rewrites patterns of (maladaptive) discomfort that you stay present with [104]. Your fear of MDMA could be unlearned if it is not an accurate representation of reality [85].
- **Loss of Control** While engagement with distressing memories can be intense, people regularly have clear, complex, and emotionally nuanced conversations on MDMA [63, 230]. MDMA creates intense feelings of compassion and safety that make aggressive behavior unlikely. D. Nutt et al. [223] ranked drugs by expert perception of "Harm to others", and MDMA was ranked at about 2% the risk of alcohol.
- **Drug Stigma** Many drugs are harmful, however, during the War on Drugs a wide variety of psychoactive substances were further stigmatized and categorized as harmful without clear evidence-based distinctions regarding their actual risk [7, 223]. While there were complex motivations for the War on Drugs, it functions and persists primarily as moral panic, a means to punish certain groups of people, and a means for politicians to disenfranchise and ostracize the voter base of their political opponents. There is little correlation between the legality of psychedelics and their potential for harm [223].
- **Addiction** A panel of medical experts organized by the Dutch government found no cases of MDMA addiction in Dutch treatment centers and concluded that "It does not, or only minimally, lead to abuse, dependency or use-related disorders." [303]. Withdrawal has not been found in rodent studies, even at extreme dosing schedules [251]. However, MDMA, like most experiences that can make you feel profoundly safe, can potentially be psychologically addictive when it is used to escape from difficult feelings rather than engaging with them. Reports of behavioral MDMA addiction in recreational contexts exist, but as previously stated, seem rare and associated with escapism [92]. As previously discussed, there have been many flaws in studies on MDMA abuse. Consequently, little is known about the effects of abusing MDMA, or what level of use causes physical or psychological problems. If you are worried about your potential for addiction, we suggest: only possessing one dose at a time, only obtaining MDMA from a trusted mental health professional who can monitor your abuse potential, don't escalate dosing, don't do solo therapy, and only use it for therapy.
- **Neurotoxicity** Some observational human studies and controlled high-dose animal studies have found that MDMA use is associated with neurotoxicity (oxidative stress in this case) or cognitive problems [230]. However, these problems have not been found in controlled studies in humans [130]. The human observational studies that find problems usually fail to adequately control for multiple-drug use, a significant risk factor. Notably Halpern et al. [130] found no long-term cognitive effects of recreational MDMA use in a population that had exceptionally low lifetime use of other psychoactive substances. The animal studies that found problems typically used extreme doses, extreme

frequencies of dosing, or injected the medicine, a more potent method of administration than swallowing a pill [230]. It's also not clear that humans would respond the same way as rats to an equivalent dose. It's possible that replicating these conditions of extreme doses or frequency of use could cause harmful neural oxidative stress in humans. Some studies have reliably found serotonin system alterations in humans, but as far as we are aware, it hasn't been established that this is clinically significant, and the effect decreases with abstinence [123]. Fear and misinformation about MDMA is widespread due to the War on Drugs, sensationalized of poor quality research, and misattribution of MDMA-related deaths as an inherent risk of MDMA instead of its interactions with certain medications and health conditions, and the risks of heat illness or hyponatremia at raves [230]. See chapter "The Toxicity Debate" in *The History of MDMA* by Torsten Passie for a comprehensive review of the topic.

High doses of certain antioxidants, including alpha-lipoic acid, ascorbic acid, and acetyl-L-carnitine, administered shortly before and during the session, prevent oxidative stress in rats [4, 12, 275]. Some companies bundle these antioxidants together in commercially available products, but we are not aware of them having been rigorously tested for usefulness in humans [252].

- **Is MDMA a Natural Substance?** MDMA (3.1) is generally made by making several modifications to the plant compounds safrole (3.2) or piperonal (3.3) [94, 308]. When properly conducted, this process results in pure MDMA. Single-substance purity greatly improves the ability to produce accurate and safe doses. MDMA test kits are useful if you don't trust the source of your medicine, though laboratory testing (like Kykeon Analytics [168] or Energy Control International [90]) is better (we have not vetted these particular services). Refer to Ruggeri [258] for a nuanced discussion of what "natural" means. For those concerned about the pharmaceutical industry: MDMA was first made in the early 20th century by Merck as an intermediate product with no recognized use itself [230]. The first known human use of MDMA was in the early 1970's as a legal alternative for MDA in recreational use. Its first use in therapy occurred in the late 1970's after the independent chemist Alexander T. Shulgin realized it's therapeutic potential and introduced it to the therapist Leo Zeff Ph.D., who used it with many clients and taught many therapists how to use it. Then, once it was made illegal, legal therapeutic use ended. Making it legal again would require enormous amounts of money to run proper FDA-approved clinical trials, but no regular drug company was willing to do this because the original patent expired in the 1930's and they wouldn't be able to recoup their investment through drug sales. The 21st century clinical trials were funded through a combination of 1) donations to the nonprofit Multidisciplinary Association for Psychedelic Studies (MAPS) and 2) MAPS selling shares of its for-profit division Lykos [239]. To recoup their investment Lykos tried to patent a specific particle size of MDMA crystals within a pill, but the patent office rejected it. Their business plan is now unclear. We think that in 2025, outside of rare clinical trials or limited legal use in certain countries, all MDMA used in therapy is ultimately sourced from underground chemistry labs and has nothing to do with Lykos or MAPS.

- **Can I Inadvertently Unlearn a Healthy Schema?** As stated by Ecker [84]:

When two mutually contradictory schemas are juxtaposed consciously, the schema that more comprehensively or credibly models reality, and therefore more usefully predicts how the world will behave ¹, reveals the other schema to be false, and the falsified one is immediately transformed [reconsolidated] accordingly.

The reconsolidation process doesn't imply that your post-reconsolidation beliefs will be a precise truth about the world or yourself, only that it will be more true than the falsified/unlearned schema in the context of your lived experience. We think this generally produces good outcomes, but is not perfect. There might be rare situations where a healthy but false-according-to-your-lived-experience schema is unlearned. For example, someone's especially deep desire to not be alive might be able to contradict their desire to, say, avoid falling off cliffs. In that case their avoid-falling-off-cliffs schema would be an un-integrated remnant from a time in their life when they did want to be alive. In case such a scenario is actually possible, please do not try to unlearn any schemas critical for keeping you or any other being safe. Do not conduct MDMA-therapy in acutely dangerous situations where healthy avoid-danger schemas may be activated. We are also hopeful that using MDMA's compassion, connection, and safety to facilitate reconsolidation of one's own fears and insecurities also tends to result in schemas that are associated with more compassion, connection and safety. On a practical level, we are unaware of any instances of MDMA-therapy unlearning a fundamentally healthy schema. The closest example we are aware of is therapeutic destabilization, where you might go through a period of increased dysfunction even while certain schemas are becoming healthier.

Similarly, the reconsolidation process can't always help you help you unlearn erroneous beliefs that were formed from unrepresentative sets of experiences. If you were the first human to meet aliens and they attacked you, you might reasonably learn "these aliens are dangerous," and no amount of reconsolidation will change that until you acquire contradictory knowledge (maybe you learn that that alien happened to be a pirate and all the other aliens are very nice people).

3.2 **Professional Guidance vs. Self Guidance

MDMA-therapy can be successful in a wide variety of contexts including therapist-guided sessions with pre- and post-session support, do-it-yourself couples therapy, and solo therapy [63, 140, 212]. However, we believe working alone with MDMA presents higher risks and a lower healing likelihood compared to partnering with an ethical, skilled, and well-matched therapist or guide. That being said, it is often difficult and expensive to access an ethical, skilled, and well-matched therapist or guide, so that may not always be the best option

¹The phrase "predicts how the world will behave" may be confusing here, but it includes beliefs about yourself (e.g. I am good, I am bad) and how you react in various situations (e.g. dogs are threatening enough to trigger a [fight-or-flight](#) reaction).

available to you. Per our individual and clinical experience, an ethical, skilled, and well-matched therapist or guide may provide:

- A trustworthy presence that creates a greater feeling of safety, enabling more effective healing
- Additional perspective that's hard to see from a first-person view
- Education on [trauma](#), healing, trust, what healthy relational patterns look like, and healthy ways to deal with emotions (also known as psychoeducation)
- Troubleshooting for problems with the medicine or other parts of the healing journey
- Improved screening for [contraindications](#) (conditions that make MDMA particularly risky)
- Monitoring of your level of [destabilization](#) over time
- A skilled and experienced perspective about how best to maintain your to your [window of tolerance](#), and broaden your window of tolerance over time
- Assistance in learning appropriate coping strategies
- Assistance identifying which coping strategies are best for you in a particular context
- Assistance preparing executive function supports for yourself to maximize your capacity to use the right strategies at the right times
- Management of destabilization periods to reduce disruptions to your life—including empathetic encouragement to rest or cut back from other obligations when appropriate, in order to preserve over-all wellness and capability, and assistance strategizing ways to manage your life that will minimize disruption
- Guidance through difficult therapeutic exercises
- An empathetic and [grounding](#) presence while you think through major life decisions, relational challenges, and challenging new [schemas](#) that may emerge in the course of the work
- Assistance identifying supplementary treatment modalities that are likely to be most effective for your situation, and in some cases, information about how best to access those treatment modalities
- Assistance in planning for your medicine experience and organizing appropriate social support for the whole process
- Unadulterated medicine and/or some degree of medical monitoring, depending on who you're working with

Therapists and guides who are ethical and skilled but who's style or personality are not a good match for you should be easy to approach about this [mismatch](#), and they should recommend you to any colleagues who they think would be a better match. We think the risks inherent in working with an ethical and skilled therapist or guide who you don't match well with mostly involve wasted time and money, and possibly demoralization. However, we think the risks of unethical or unskilled therapists and guides can include:

- Emotional, physical, financial, or sexual abuse [221]. This includes [Adverse Idealizing Transference](#) (See Section 3.3).
- Excessive dependence on that therapist or guide [221]
- Increased risk of adverse effects and destabilization, possibly though overly intense or frequent [psychedelic](#) sessions with minimal support.
- Ineffective treatment that the mentally healthy would find frustrating could be totally demoralizing to the mentally unhealthy. You could stop seeking any kind of treatment altogether.
- They may push their own interpretations on you while you are in a suggestive state of consciousness, potentially leading to false beliefs of abuse [270] or false beliefs about how trauma and mental illness work.

Individual and couples MDMA therapy without professional assistance (possibly with the assistance of a trusted, empathetic, and emotionally non-reactive sitter [295]), appears to work well for some people, including the author MG [63, 140]. We are uncertain what circumstances lead to positive vs. negative MDMA therapy without professional assistance, and the degree to which various risks are increased. We can't say if this is appropriate for your particular situation, but it is an option that a lot of people like.

We propose the following ranking of options. The top of the list represents the lowest risk of adverse outcomes, the highest likelihood of durable healing, and also the highest financial cost. This list is a general guide and the exact positions of items are debatable, as well as dependent on personal circumstance. Exceptions to the rule always exist.

1. Continually working with a skilled, ethical/accountable, psychedelic-trained therapist or guide you align well with. *We tentatively think this is the ideal model for all situations if you can find the right clinician to work with and have enough money. We also think this model is especially important for people with potentially dangerous symptoms they can't manage themselves, including psychosis, mania, suicidal ideation, or a severe lack of impulse control.*
2. Start off with a skilled, ethical/accountable therapist or guide who you align with and who is psychedelic-trained and/or personally experienced with MDMA. You may later transition to self-guided sessions (with regular check-ins) if you and your clinician collaboratively decide that is sufficiently safe for you. *This model has not been explored in the research and may have a higher risk of difficulties. However, because it offers dramatically lower costs and there are many anecdotes of people (including MG) who have found it highly effective, some people will pursue this method.*

3. Work with a skilled, ethical/accountable non-psychedelic-trained therapist or guide you align well with; collaboratively assess your risk-factors with them (perhaps reading this safety section of this guide together, or consulting briefly with a psychedelic trained therapist). If your risk factors are low, you then self-guide all your medicine sessions while maintaining regular sessions with your clinician. You also use high quality resources (see Section A) to educate yourself on the nuances of effective and safe MDMA therapy and use a high-quality sitter as appropriate, which includes at least the first several sessions (See Section 3.7 for characteristics of good sitters). *We think this model is similar to the previous one, but—depending on the quality of your self-education—somewhat more difficult and riskier.*
4. Self-guide all your medicine sessions and do all of your own integration work, perhaps talking about your healing journey with emotionally skilled friends or friends skilled in safely using psychedelics for healing. You also read literature (see Section A) on trauma healing and psychedelic therapy written by mainstream academics and use a trusted sitter for at least the first few sessions (See Section 3.7 for characteristics of good sitters) *We don't generally recommend this model because self-assessment of risk factors is very difficult. If you decide to try it anyway, we think you will greatly benefit from high self-emotional knowledge and high skill in managing your own emotional reactivity. While this model has worked for many people, we are unsure of the risk/benefit trade off. We strongly recommend identifying and at least briefly connecting with a therapist or guide you might want to work with in case you get into deeper water than you are comfortable with.*
5. Self-guide all your medicine sessions and do all of your own integration work. You don't use any high quality reference material and don't understand the technical nuances of safe and effective healing. Or you work with an incompetent or abusive guide or therapist who may harm you by suggesting overly-intense psychedelic sessions and not effectively help you with the resulting trauma or destabilization. They may also offer distorted or unhealthy interpretations of experiences you have during a session. *We don't recommend this in any circumstance. While it is occasionally helpful to some, we think the lack of rigorous understanding of the process can place both safety and healing at elevated risk, and is likely to impair healing to some degree. Adverse effects may not be identified, understood, and well-managed.*

It seems important to note that although more data is needed, therapeutic use of psychedelics in professionally supported group sessions, where multiple therapists look after a larger number of clients throughout a medicine experience, may offer a potential way to make professional support more accessible [196].

3.3 **How to Find a Therapist or Guide

Which therapist you work with matters a lot. For instance, in a large study done by Firth et al. [108], after adjusting for demographic factors (like the severity of symptoms clients were entering therapy with), the best 3.9 percent of clinicians had 77.2 percent of their

clients recover; the recovery rate for therapists in the average range was 58 percent; and the 3.9 percent of clinicians who had the worst outcomes only saw 41.4 percent of their clients recover (Note that a significant percentage of people recover even without therapy, so it's possible that the worst therapists have a negative influence on their clients.).

It is our hope that the following recommendations, which largely emerge from our personal and clinical experience ², can make finding a therapist feel less overwhelming and more hopeful for those who are struggling—or who don't even know where to start—with the search.

First, we acknowledge the difficulty: even under optimal circumstances, accessing mental healthcare can turn out to be a slog. These challenges are common knowledge for people who provide community mental health services and/or who have accessed them repeatedly: the financial and administrative costs are often daunting. Interacting with licensed mental healthcare professionals is inherently vulnerable for many, especially those who have witnessed or experienced carceral hospitalization or forced medication. Intake interviews often demand intimate details of one's finances, sexuality, and medical and mental health. All of this is the price of accessing a clinical relationship that may or may not be very helpful. If it isn't, clients may feel they need to stick with it, because they do need help, and finding someone else to help them seems like more than they can take on. . . . but that doesn't necessarily mean the clinician will stick around—and particularly for those who are using medicare/medicaid or who require less-expensive sliding scale services, clinicians may be students whose clinical internships end only a few months after starting to work together. Online services, which have endeavored to bridge the gap between what is needed and what is easily available, are plagued by serious ethical and product-quality concerns [18, 27, 32, 33, 110].

The good news is that there *are* excellent clinicians out there—and not all of them are late in their careers. Early career therapists, like those who tend to staff more affordable clinics, provide just as good of care as their more experienced counterparts [121]. Here are our recommendations on how to find one that's right for you.

Bad Therapy is Worse than no Therapy

Remember that really bad therapy can really hurt you [144], and as such we feel it is worse than no therapy. Bad therapy can leave you stagnant for a long time with the impression that no real help for you exists. It can make your symptoms worse without making them better after. In the worst case scenario, it can leave you with additional [trauma](#). See Section 3.3 for a discussion of the particular challenges of avoiding negative and damaging clinical experiences in the realm of [psychedelic](#) therapy.

Good therapy is often very uncomfortable [85]. However, you should feel a sense of mutual trust and respect with your clinician, and you should also feel a sense of collaboration and consent regarding the goals you are working towards and the methods you use to get there [126]. Even if you don't understand the methods your clinician is using to help you, we

²This experience includes some common knowledge of professional norms among the licensed mental health professions, much of which can be found in the ethics codes of the major licensed mental health professions, e. g. the National Association of Social Workers code of ethics, the American Psychological Association code of ethics, the American Counseling Association code of ethics, The American Association for Marriage and Family Therapy code of ethics, etc.

believe a skilled and well-matched clinician will take the time to help you develop a trust in them that is commensurate with the discomfort of what they are asking you to undertake.

Although we cannot speak to the specific trade-offs of your situation, in general we recommend continuing to search until you are able to access good therapy.

Trust your Personal Experience

Trust your perceptions, because your personal experience of your clinician impacts the efficacy of your treatment [145]. You don't just need a good provider, but a good provider who is also a good fit with you. We strongly recommend using the BR-WAI [126], an empirically validated tool for understanding how you and your therapist are connecting, and what might be required to improve that connection.

In our experience, it's a good idea to look for someone it feels like you could say anything to. If you cut your arm, any skilled emergency physician will be able to competently stitch you up. The same is not true with a comparable degree of psychiatric injury [108]. In mental healthcare, the bedside manner is part of the intervention, and the same bedside manner doesn't work for everyone. Although the most skilled mental healthcare providers connect well with an extremely broad spectrum of clients, it is unrealistic to expect every provider to "click" with every client—and many excellent mental healthcare providers ultimately focus narrowly on particular populations of interest to them. If you aren't connecting with a particular clinician, it doesn't mean anything is wrong with them, and it doesn't mean anything is wrong with you.

Feedback

Good therapists love feedback and direction. It is very likely that many therapists who could do great work with you if you are expressive about what you need and want would, in contrast, be very bad therapists for you if you aren't expressive about those things [74, 170, 190, 224]. If you can, we recommend asking clearly for what you want and talking clearly about how things feel. Additionally, there are several instruments that have been developed to help therapists measure and improve their performance. Examples include the BR-WAI, the ORS-SRS, the Core-OM, or the QR-45.2. If your therapist asks you to participate in one of these formal feedback mechanisms, we recommend doing so, even if it feels awkward; these measures really seem to help therapists provide better services.

We've observed that it is sometimes helpful to imagine what therapy would be like, if it went as well as you could possibly imagine, and to share this with your clinician—and to articulate your fears about the process. You can also ask if your ideal hopes align with their experience of their methodology, which may help you set expectations for your treatment. You can use the list above (of what a skilled therapist can provide) to identify ways you would like your therapist to support you. It may be helpful to identify which forms of support you are interested in receiving, and to spend some of your initial sessions learning how your clinician feels about providing support in those particular ways.

Particularly if you have been working with a particular clinician for awhile and your issues/diagnoses and demographic are within their main practice area, you are *well* within your rights to ask a clinician to go outside their comfort zone to learn or implement a new-

to-them intervention that is right for your situation. An accredited therapist is required to complete continuing education hours anyway. There are lots of legitimate reasons they may say no (cost, time, and accessibility of additional training, to start with), and that's OK too—but please don't be afraid to ask.

If things aren't working and you've made some effort to recruit your clinician's help in fixing the situation, a therapist may also be willing to spend some of your final few sessions helping you find and connect with someone who is a better fit for you.

Boundaries

Good therapists have good boundaries. Clients often come to therapy without an understanding of what healthy therapeutic boundaries are and why they might be important, and that's OK—it is the clinician's job to have this knowledge, to share it with the client, and to assert boundaries as needed.

One of the most important reasons boundaries are crucial in therapy is a phenomena called [Adverse Idealizing Transference \(AIT\)](#) [76, 144]. Idealizing Transference is a phenomena in which clients develop strong positive feelings towards their therapist. This can be totally healthy and extremely helpful to the course of therapy—supporting clients in their sense of safety and their ability to sustain focus and effort through the sometimes severe discomfort of healing. However, in some cases, it is possible for these positive feelings to be so strong and misdirected that they cause considerable harm—causing lasting distraction and disruption in the client's life, potentially continuing for decades. This situation creates a severe vulnerability that the therapist, if they are unscrupulous or unskilled, may exploit (intentionally or not) for emotional, sexual, or financial gain—creating severe trauma for the client and sometimes impacting others as well. In these cases, Idealizing Transference has become Adverse Idealizing Transference. Just as helpful medications sometimes have side effects for a small percentage of the people who use them, a small percentage of therapy consumers experience AIT.

AIT can happen even when a clinician is doing everything right [76]. However, both the emotions of AIT and the harm created by them can be greatly amplified when therapists fail to communicate and follow through on healthy boundaries. Here are some commonly recognized healthy professional boundaries for therapists:

- The clinician does not disclose details of their personal life to you unless that disclosure enhances your treatment and is motivated by a desire to promote your welfare.
- The clinician avoids dual relationships wherever possible. For example, if a client cannot pay for services and offers to do yard work or provide other professional services in barter, it would cause a dual relationship to accept this offer. The most commonly accepted exception to the dual relationship rule is in extremely rural practice, where access to services is very limited—so, for instance, a clinician might provide mental health services to someone who also their children's pediatrician. However, in these cases, other professional boundaries should still be maintained on both sides.
- The clinician is very clear from the beginning of treatment about their policies regarding the location and timing of sessions, confidentiality practices, means and quantity

of payment required, acceptable communication channels outside of therapy sessions, contact on social media, contact outside of the therapy context, and lateness or missed sessions. The clinician follows through on these policies as stated, and communicates any policy changes in a timely way.

- The clinician does not communicate to you in any way that they feel differently about you than they do about their other clients, or that they treat you differently than their other clients.
- The clinician does not permit or encourage the exchange/offering of significant gifts, especially financially significant gifts.
- The clinician does not provide advice outside the realm of their expertise; most clinicians minimize the time they spend giving advice even within their expertise, because supporting clients in the process of arriving at their own conclusions is more aligned with ethical standards and more effective towards lasting change.
- If physical touch is engaged in at all, it generally should be minimal, such as a brief hug at the end of each session or a single brief hug at the termination of treatment. Physical touch may be avoided entirely, and if present must be for the benefit of the client, not the clinician.
- Even if the clinician is providing therapy on a very generous sliding scale basis that is essentially free for an individual with great financial need, it is a good sign if they insist on always charging a fee. In many cases, a fee less than a dollar can still serve as a healthy reminder about the nature and boundaries of the relationship, helping both client and clinician maintain a mindset that minimizes the risk of AIT.

Therapists are, unfortunately, not explicitly educated on AIT at this time. (We strongly recommend that all clinicians read the two reference articles for this section). That said, therapists in all of the major licensure categories should be familiar with and generally compliant with the boundaries listed above; understanding the importance of boundaries and respecting the vulnerability of clients are important topics in their clinical training.

Per item 3 on this list, if you are a client with a high number of risk factors for AIT [76, 144], we recommend discussing preventative measures with your clinician, and weighing boundary practices particularly heavily in your assessment of clinicians' fit for you. Note that these risk factors are not required in order to develop AIT, nor do they guarantee AIT—they simply correlate with an increased risk. The risk factors are:

- a history of dependent/idealized relationships, especially with health professionals
- an approach to therapy that is primarily seeking care, rather than insight
- unrealistic views of what therapy can provide
- being female, especially if working with a male therapist who is older than you
- having a therapist of a gender you are sexually or romantically attracted to

- being a sexual minority, or
- experiencing significant symptoms on a spectrum with borderline or narcissistic personality disorder

A final recommendation on boundaries and the prevention of AIT: although confidentiality is an important therapeutic boundary, we feel it is an excellent sign if your clinician seeks regular supervision and consultation (without disclosing more details of your case than must be disclosed to obtain appropriate professional advice) as needed. Neither you nor your clinician should feel that anything is happening in the therapy room that they would be ashamed or embarrassed to disclose to a trusted friend (in your case) or a trusted HIPPA-compliant colleague (in theirs). Therapy should feel private, but if it starts to feel like a secret, something may be off.

Targeted Therapy

In our experience, in some circumstances it is very important to seek therapy that is targeted to the challenges you are experiencing. One of the most common and arguably benign forms of bad therapy happens when clinicians offer a generally empathetic and supportive environment without bringing clients into a space of productive discomfort. This often results in therapy that feels pleasant, but not very helpful—and which perpetuates the damaging myth that working with a skilled mental healthcare provider is interchangeable with, but more expensive than, having an empathetic friend.

Although the current diagnostic system is substantively flawed [60, 83], we do recommend that a best practice for seeking effective mental healthcare is to a) do one's best to obtain one or more accurate diagnoses, b) research the most evidence-supported treatments for your diagnoses, and c) seek out clinicians who are trained and experienced with those specific treatments—ideally, who are experienced using those specific treatments to address those specific diagnoses. According to both our personal experience and Thomas Insel, M.D. [163], this leads to radically better outcomes than a less targeted search for mental health treatment.

A less medicalized approach to this process recommended by a colleague [280] is to identify what kind of change you would like to make with the the help of a professional, do some research on how people seem to be working towards that change in various contexts, and seek out a professional who has a good reputation or training in that method. This may be especially appropriate if the help you are seeking is not specifically oriented around mental illness.

Regardless of whether this whole sequence feels accessible to you, we recommend if you are experiencing therapy that feels pleasant but not as helpful as you need it to be, it is worth having a conversation with your clinician about what specific interventions and modalities they are employing, and what might work better. Often, in this situation, you as a client are in need of a treatment method that will push you more.

Finding a Therapist can be a Long-Term Project

If you feel daunted by the process of finding a good therapist, we strongly encourage you to recruit some support and treat finding a therapist as a long-haul effort. For example, if you have a supportive friend or partner, you could ask them to commit to providing you with your favorite takeout every time you complete ten or fifteen "actions" (getting a list of clinicians your insurance covers, leaving a message with a therapist to see if they are taking clients, completing an intake interview, scheduling a session, completing a session, etc.) on your therapist search. Alternately, you might start a text thread with your closest supporters, where you can report your efforts and be rewarded with gifs and emojis. A perspective shift that may be helpful when searching for a therapist is to regard each "failure" or action as a step towards finding the help you need, worth celebrating even if it doesn't yield any immediate tangible results.

We recommend completing three or more sessions with a given therapist before committing to give treatment with them a try. If you luck out and find a great fit on your first or second try, the BR-WAI will help you have confidence that you've really found what you're looking for. If a particular clinician (or a string of clinicians) are not a fit for you, that's OK too; that doesn't mean you have anything to apologize for. It's good to trust the process and expect that it may take some time.

We don't know enough to endorse them, but Psychedelic Passage [240] offers a psychedelic guide/therapist referral service. You may be able to find guides and therapist from talking to people at psychedelic meetups, though quality and adherence to ethical standards may be variable.

Accreditation and Safety

We would be remiss not to acknowledge that unlicensed³ or minimally accredited mental healthcare providers are common [2]—often billed as coaches, guides, shamans, pastors, or simply healers. In this era when a mass-scale mental health crisis is met with a healthcare affordability crisis in the USA, individuals in need of healing seek assistance wherever they can. Indeed, talk therapy and psychiatry are modern inventions, and we are aware both from common sense and through personal experience that skilled and ethical healers of mental and emotional distress exist across many contexts and training levels.

That said, it can be extremely difficult to verify whether the individual you are considering working with is ethical and skilled—and working with an unskilled or unethical provider can be extremely harmful [144, 207]. Although the protection offered by working with a licensed counselor is imperfect, we feel it is an extremely important consideration—and all the more so, as described below in Section 3.3, when working with psychedelics.

We perceive significant risks associated with using an unlicensed mental healthcare provider:

- They may provide, and charge for, interventions that are useless or harmful.

³For the purposes of this section, when we say unlicensed, we are not referring to pre-professionals and pre-licensed professionals who are operating under the license of an independently licensed professional as part of their training progression. Examples would include a resident counselor or psychologist. In terms of accountability and ethics enforcement, we feel comfortable recommending this class of providers at the same level as independently licensed professionals.

- They may not have been trained in differential diagnosis, and in any case are not legally permitted to diagnose you
- They may provide services to you while they are impaired through the use of drugs or alcohol
- Because they may not have received training about the importance of boundaries and of respecting the vulnerability of clients within the power dynamics of mental healthcare, they are less likely to express and enact boundaries and other practices that minimize the risk of adverse idealizing transference (AIT).
- As such, they may enact harm that emerges not from the interventions themselves, but from other aspects of how they do business: for instance, unnecessary dual relationships or boundary violations can leave clients feeling dis-empowered, violated, or humiliated across multiple domains of their lives.
- They may encourage you, during particularly vulnerable and suggestible times, to make decisions that are bad for you and your life; they may leverage their intimate knowledge of your trauma to exploitatively encourage you to make choices which benefit them at your expense.
- Unless they commit crimes in a way that would be recognizable as criminal and punishable by law even outside of a therapeutic relationship, they are unlikely to experience any negative consequences for any physical, financial, or psychological harm that may come to you in their care.

The protections provided by working with a licensed professional are extremely imperfect. For instance: the field of mental health talk therapy is still relatively young, and it is widely accepted that talk therapy is as much art as science. We have observed that most fully licensed professionals center their practices on interventions that could be covered by insurance, and this may provide some probabilistic guardrails against interventions that have no empirical support at all. However, even among fully licensed practitioners, there is little enforcement that compels clinicians to focus on the most empirically validated interventions, to deliver them in the most empirically validated ways, or to be able to match a client's particular situation to the most empirically validated treatment for that specific situation. If these practices are important to you, we recommend asking many detailed questions about them when you are searching for a well-matched therapist.

Additionally, we have observed that various systems of power and oppression can and do play out in the therapy room if clinicians are not actively, vulnerably, and skillfully working to avoid this outcome. The prestige and respect generally afforded to therapists can sometimes foster hierarchical and non-collaborative dynamics. Therapists sometimes say extremely inappropriate, dismissive, harmful, and/or stigmatizing things, and clients are harmed the more by it because those statements were made by a therapist—someone who they perceive to be an expert, someone who is supposed to have the answers. Licensure does little or nothing to protect against or prevent these forms of harm.

Although cultural acceptance is improving, mental illness is still very stigmatized, and there are many reports of clinicians who turn on their clients, abusively labeling them "borderline" or simply crazy, if those clients file a complaint against them [144]. The privacy of the therapy room, the power of stigmatized diagnoses, and the prestige of the therapist role means that in "he said she said" adjudications, a client is unlikely to be listened to. The situation is further complicated by the reality that in the process of a long career working with many clients who suffer from profound attachment wounds, overwhelming trauma, and at times delusions, hallucinations, and paranoia, clinicians' fears of being misrepresented and attacked by clients as a symptom of their illness are not always unfounded [128, 321] It is inherently very difficult to tell from the outside—and sometimes from the inside too—what has really gone on. As such, many therapists may be more likely to empathize with their peers [144] than wronged clients when they hear about misconduct by colleagues. This unfortunately creates a robust haven for a minority of clinicians who are unethical⁴, extremely incompetent, negligent, and/or predatory.

Despite these shortcomings, we feel it is important to highlight the advantages of working with a licensed clinician, and encourage you to weigh the risks very carefully. Some certificates for coaching or christian counseling can be obtained in a few weeks to a month for less than a thousand dollars; these kinds of certifications do not bring significant professional accountability, because a) loss of such a certification doesn't usually create significant occupational impairment, and 2) certifications this small are not typically backed up by a licensure organization with sufficient resources to keep track of practitioner misconduct or enforce consequences [50]. Obtaining independent licensure as a mental health clinician demands years of study, additional years of supervision, and an often six figure financial investment in education and accreditation. If a fully licensed professional practices therapy while they are impaired through drugs or alcohol, or if they cross sexual boundaries with a client, or if they exploit clients for financial gain—for instance, by giving financial advice or creating a dual relationship—the client can file a complaint with the clinician's licensure board [26, 316]. If the clinician is then found to have committed the harm described in the complaint, they may (depending on their particular license and jurisdiction) face a variety of consequences. Here are a few of the possibilities:

- They may have their name published on a state registry that lists the misconduct they were found guilty of
- They may be required to take ethics classes or complete other professional development work
- They may be required to work under a supervisor for a period of time, and during that time announce to every single client at the start of treatment that they are working under the license of another professional and who that professional is
- They may lose their access to providing treatment through a hospital they had previously worked through, or they may lose the ability to have their work reimbursed through insurance

⁴"Studies generally show remarkable consistency in age, gender, and practice characteristics in that the typical transgressor [of sexual relationships with clients] is a middle-aged male therapist in solo private practice who engages in a sexual dual relationship with one female patient" [52]

- For severe and/or protracted misconduct, or if they refuse to comply with rehabilitation requirements, they may have their license entirely revoked

Independently licensed clinicians must typically pass a criminal background check to become accredited [81]. They may also lose their accreditation if they are found guilty of fraud, sexual misconduct, or abuse in other areas of their lives [26]. This is an important safeguard because a pattern of exploitation across various domains of their life is one of the earmarks of an individual who is genuinely predatory, rather than simply incompetent [65]. Although these consequences are not always commensurate with the harm caused, at least one study has shown that the process of filing a board complaint against a harmful clinician on the whole tends to be a positive experience for survivors [316].

To check whether your clinician is licensed or accredited in some way, try asking them for their license number and then looking it up on the website of their professional association. There are also several professional directories—Psychology Today being the largest in the United States—that will only list clinicians after verifying their credentials. In the United States, there are *many* qualifications and certifications that allow a practitioner to legally provide mental health counseling.

To further add to the confusion, we have observed that even within the same license, training can vary widely. If you are committed to working with a licensed professional, we recommend searching for providers based on the professional's experience, preferred client demographic, and/or treatment modalities, and then verifying their license. You can attain a clearer understanding of the details of a particular clinician's background with the particular issues you are having (or the particular modalities and interventions you are interested in being treated with) by asking them detailed questions. For example: how many clients have you worked with who have x diagnosis? What is your training and background in y intervention? They might answer with details including trainings or continuing education units they have completed, books they have read, classes that were part of their degree, relevant experience with those populations before they became a therapist, and much more. All these details are highly variable between individual practitioners, but the baseline safety protections that come from working with a licensed professional are always attached to the specific license they hold. Finally, please note that the fields of life coaching, guiding, or other unlicensed professional support often serve as havens for individuals who have lost a license due to misconduct.

If you choose to work with unlicensed professionals, we recommend exclusively working with professionals who are very clear about their scope of care, and who participate in accountability and transparency practices such as participating in accountability pods (a practice developed by the Bay Area Transformative Justice Collective, see Mingus [209]) and publicly posting their business ethics (as exemplified here: Sinback [279]). Indeed, we feel these practices, though imperfect, are a green flag from providers of any licensure level, and we hope they will become normalized across mental healthcare—along with providers routinely seeking appropriate supervision and consultation, and being transparent with clients about who is supervising or consulting with them. Finally, many of the suggestions from the "Recommended individual actions to improve safety of psychedelic care" section may be adapted to reduce your risk profile, even if you are not working with psychedelics—and the caveats we placed on that list apply here as well. No matter who you work with, if they

choose to harm you through their behavior, that is not your fault.

To understand scope of care, when you are considering working with an unlicensed professional, it may help to ask many detailed questions about precisely which services they provide, and about how and where they learned the skills to provide those services. Unlicensed professionals are forbidden by law from diagnosing or treating mental illness but many of the interventions that are used to treat mental illness can be appropriately implemented by unlicensed professionals, and have many legitimate uses outside of mental illness treatment [2, 154]. For instance, some coaches teach people how to [reconsolidate](#) maladaptive [schemas](#), or how to complete thought records, or how to use the mindfulness-based RAIN (see Brach [37]) practice to ride out urges to engage in maladaptive coping, or myriad other skills and strategies that constitute legitimate mental illness interventions. These skills are not exclusively relevant to mental illness; a reasonable person might learn them simply to enrich their life and increase their personal growth. When unlicensed professionals deploy them, they are also not doing so (or legally should not be doing so) in the context of a treatment plan wherein a therapeutic relationship is constructed and interventions are performed that will specifically address a specific mental illness. As such, it can reasonably fall within the domain of unlicensed care to teach these skills, and to help folks identify some circumstances where it is helpful to use them. These kinds of services may significantly help you self-manage or self-treat your mental illness, especially (as is often the case) if you are unable to access high quality licensed mental healthcare.

On top of this, we've observed that coaches and other unlicensed professionals are often an appropriate option for bridging a gap between the needs of people with mental illness, and the necessary level of support (often, more than meeting with a clinician once a week) that would allow them to achieve a significantly better quality of life. For example, a coach might call you several times a week at the moments in your schedule that you have determined you are most vulnerable, so they can help you accomplish some task initiation or avoid some doom scrolling—a service a therapist is unlikely to provide. Unlicensed professionals might help you with more practical, seemingly superficial, yet crucial aspects of changing your life for the better: sitting with you while you fill out job applications, or de-clutter your house, or practice eating mindfully. Some unlicensed professionals can help you learn and apply healthy relationship skills that will radically improve your life. Some carry out structured and empirically validated approaches and work under the supervision and organizational support of fully licensed professionals, as exemplified by the Healthy Gamer coaching programs [153].

In contrast, we believe the very best mental health professionals can complete a detailed bio-psycho-social assessment of your over-all situation, accurately match your symptoms to one or more diagnoses, and then offer you mental health interventions that are particularly suited to you in the context of that larger picture. They offer a deep understanding of how various constellations of symptoms tend to show up, and some awareness of pitfalls you are likely to encounter along the way based on that. They will have an understanding of what level of care is appropriate to your situation, and if they do not have the particular expertise appropriate to your condition, they will help you find a provider who does. They may know much sooner than you do if it is urgently important for you to receive a higher level of care—for instance, early intervention for a first psychotic episode has a massively positive impact on the lifelong trajectory of individuals psychotic spectrum disorders, and timely intensive treatment for eating disorders or substance use disorders can be lifesaving. Particularly if

you do not have a case manager to take on this role, a mental health professional may help you work through what is stopping you, and learn the skills to recruit and coordinate care from many sources. Examples include:

- a psychiatric prescriber
- specialist care providers like a dietitian or a trauma informed OB-GYN
- peer support from friends and loved ones
- peer support from potential future friends and loved ones, as when joining an activity group that helps you stay consistent with positive coping strategies
- community programs, like a senior center, meditation center, or gym
- coaches, ecclesiastical leaders, or other appropriate unlicensed professionals
- when appropriate, a personal care assistant to assist with the activities of daily living

Although schema re-consolidation may ultimately heal most or all of your mental illness in a deep and durable way, in the meantime you must live with your symptoms—and build the best life you can, despite your symptoms. The best mental healthcare providers are experts, not only in addressing the root causes of mental illness, but in helping you reduce the incidence of your symptoms and in helping reduce the impact of your symptoms on your life.

MDMA/Psychedelic Specific Complications In Obtaining Professional Care

Finding professional support for psychedelic therapy carries challenges over and above the challenges of finding mainstream mental healthcare [202, 203]. The specific nature of psychedelic therapies amplifies the vulnerability of seeking psychiatric care, including (we surmise) vulnerability to AITs. Some of these challenges emerge from the legal status of psychedelic therapies. Finally, these factors have combined to create an existing culture of underground MDMA therapy that can be painfully exploitative [221]. An effective process for securing professional support must take all of these challenges into account.

Challenges caused by the vulnerability of seeking psychiatric care: As discussed in sections 3.3 and 3.3, there is a severe power imbalance between providers and consumers of mental healthcare. When a fully licensed professional enacts behavior that is very clearly abusive, it creates the case in which we would expect the maximum possible structural support for accountability within conventional criminal-legal and administrative systems. However, even in these cases, proving misconduct and enforcing appropriate consequences for it is not always possible [34]. On top of this, we’ve observed that many individuals consuming mental health care feel that they must put up with a certain degree of discomfort in order to access care they may desperately need. We find they are often understandably unskilled at detecting the difference between the healthy discomfort of effective treatment [85] and discomfort related to mistreatment or misconduct.

Challenges caused by the nature of psychedelics: As detailed below, psychedelics can increase client vulnerability. Psychedelics can create experiences of great mental and sometimes physical intensity, of much longer duration than a traditional therapy session. Long sessions, sometimes a risk factor or "red flag" for harmful boundary violations [290], are necessary in psychedelic therapy. MDMA can generate sexual feelings [199], and we think the same enhanced meaning [136], empathy, and openness to experience that make them such a fantastic aid to re-consolidation work may mean they leave individuals who take them more susceptible to persuasion. Altered states of consciousness also impair the ability to be appropriately cautious and thoughtful about risk. These factors make it even harder for clients to tell when providers are behaving inappropriately. Additionally, a significant subset of MDMA clients are having one of the peak experiences of their life, or even *the* peak experience of their life. We think this could cause therapists and guides who routinely facilitate this therapy to feel godlike. Even excellent guides and clinicians may need to work very hard, when administering psychedelic assisted therapy, to maintain appropriate boundaries, humility, and client-centered care. This dynamic can undermine even very good clinicians' ability to provide quality care. . Although there is no data on the topic, we feel this dynamic almost certainly increases the risk of AITs with MDMA therapy, particularly with providers who are not scrupulous regarding boundaries or thoughtful about preventing this specific risk. All of these aspects of psychedelics amplify the already formidable power dynamics between a therapist and a client, regardless of legal status or other factors.

Challenges caused by legal status: The legal status of psychedelics creates additional risk for those seeking professional support for PAT in several ways:

- Mental health providers' training and experience around psychedelics has been extremely limited by their legal status. This includes the ability of professionals to experience psychedelics as a part of their training, which most clients and clinicians feel improves clinicians' ability to provide psychedelic therapy, and which many feel is essential to that ability [180]. However, clinicians generally do not have access to these experience in a legal context with solid supervisory support. If clinicians even disclose their history of psychedelic use, they could theoretically face some degree of legal or licensure related repercussions—and even if the actual risk of repercussions is very low, the perceived risk may be high enough to prevent clinicians from becoming involved in these activities.
- The fact that everything has to be "underground" makes it harder for people to find each other as needed. This can create a sense of scarcity, as in, "I have found a provider and I need to stick to them because searching for a better fit feels daunting or impossible."
- When the medicines in question are criminalized, clients who are harmed while using the medicine (or in the process of preparing for medicine use or integrating afterwards) often legitimately fear legal and/or social consequences against themselves if they report crimes against them that were undertaken during this process [221]. This makes the power dynamics astronomical.

Existing culture of exploitation in psychedelic therapy: Taken together, the above factors render it unsurprising that exploitation, [spiritual bypass](#), and cultic dynamics seem to have

been woven into the culture of underground psychedelic therapy [44, 221, 241]. The suggestibility induced by psychedelic use, the profundity of experiences produced, the challenges providers face in staying humble and client centered when providing these interventions, and the deep shelter from any legal threat about malpractice that is created when it is all illegal all play a role in a culture of guides, healers, shamans, and therapists who are able to harm with impunity. Multiple accounts have surfaced of the need to develop a better framework of accountability in these underground, unregulated communities. If you are interested in learning more about this topic, we recommend the following resources:

- Power Trip Podcast [221]
- "Addressing Abuse and Repair: An Open Letter to the Psychedelic Community" [241]
- "Ethical Transgressions and Boundary Violations in Ayahuasca Healing Contexts: A Mixed Methods Study" [44]

Individual Actions to Improve Safety of Psychedelic Care

In this era of regulation, many people with mental illness are driven to work with unlicensed providers due to mistrust of the mainstream mental health system and/or the financial or logistical inaccessibility of high quality licensed care [2]. Additionally, while the system of licensed providers presumably prevents many of the most egregious violations, some serious harm can and does slip through—as evidenced by the whistleblower reports from the MAPS trials [75]. In this context, we believe there are steps some individuals may be able to take to increase their safety when seeking psychedelic therapies.

We want to emphasize that even if you do nothing on this list, any care provider who violates the sacred trust you have put in them as a healer by mistreating you is fully responsible for their own actions. We also want to emphasize that those who are most badly in need of psychiatric care are often under-resourced, and likely to find it challenging or impossible to carry out the degree of vetting or preparation they might have ideally preferred. We are not providing these suggestions to cast blame or create additional responsibilities for care-seekers, but as a resource with which those who are able may be able to improve the risk profile of their healing endeavors.

License and Certification

Research their license and certifications carefully. See Section 3.3 about accreditation and the protections it provides. Remember that practitioners may claim a license they don't have, or they may have some sort of certification that does not carry enough weight in their professional life to enforce any kind of accountability. We particularly recommend taking other precautions if your clinician does not belong to a licensing body that publishes the names of clinicians who are found to have violated its ethical code.

Evaluate Fit

Follow the advice above (see Section 3.3) about finding a clinician who is a good fit for you, including working with them for at least three sessions (preferably five or more) before making

any decisions about using their assistance for medicine work. During this time, observe their boundaries very carefully, and have frank discussions about their qualifications, your needs and expectations, and the modalities that would be employed during the medicine work.

Methodology and Expertise

Research their therapeutic methodology and expertise. It is our hope that the evidence-based theoretical framework offered in this book—positing that the primary mode of healing MDMA offers is memory reconsolidation—can assist some clients in assessing whether they are interested in engaging with various therapeutic methodologies. Accordingly, we particularly recommend seeking clinicians who have a strong background in addressing [dissociation](#) and panic, in dealing with trauma generally, and in assisting their clients at working through somatic manifestations of trauma/somatic release.

Although they may be particularly fast and effective for activating some important schemas, we strongly recommend avoiding methodologies that involve physical touch—*particularly* those that involve physical touch during the actual medicine work, when the client is unable to consent or make unbiased decisions about whether to continue or stop a particular therapeutic interaction.

If you are interested in somatic methodologies that involve touch, we recommend alternatives such as therapeutic use of restorative yoga postures. In this practice, a clinician can provide support through various bolsters and pillows, along with verbal instruction, so that there is never any need to touch you in any significant way. If for some reason you do choose to pursue a methodology that involves touch, we recommend undertaking precautions to increase your sense of volition and improve the safety of the endeavor:

- Creating a detailed written consent contract in advance of your medicine session, that determines what forms of touch will be acceptable under what circumstances and how these boundaries will be upheld
- Using witnesses and cameras to provide you with certainty that your wishes have been respected

We agree with the assertion of the American Association of Sex Educators, Counselors, and Therapists, when they suggest that there is no circumstance where sexual touch is appropriate to the therapeutic relationship [\[13\]](#).

Background Check

Get a background check on the guide and possibly on others who recommend them or who have trained them. In some cases, significant networks of recommenders or well-regarded trainers may all be invested in unsubstantiated or potentially harmful therapeutic modalities [\[221\]](#). Historically, lineage of training has been an important way that healers are credentialed in the absence of licensure systems; if your guide has trained under someone who promotes potentially harmful therapeutic modalities, with concepts such as "breaking down" the client or helping them "fight it out", or if they have been mentored by people who have a history of boundary violations against clients, we recommend proceeding with extreme caution if at

all. If a guide with these red flags seems like an otherwise excellent match, we recommend having detailed conversations about how they relate to those practices and approaches, and taking the other safety considerations listed here especially seriously. Finally, as noted in the accreditation section, if a prospective professional support has a history of fraud or abuse in other areas of their life, this is also worth taking into consideration, even though it may appear unrelated, because this may be a warning sign for truly predatory behavior.

Accountability

Look for external accountability in the clinician's ethical structure, both philosophically and practically. One of the concerns cited by Nickles and Ross [221] regarding safety in PAT is that there seems to be a cultural norm in underground psychedelic therapy of identifying the truth—including the truth about situations in which clients allege their clinicians have harmed them—as something that comes from inside each person. In contrast, healthy accountability practices require us to listen with openness to outside information which can make us feel downright terrible on the inside. We recommend seeking providers who maintain active relationships with supervisors, mentors, and/or accountability pods [209] who can help them receive the report appropriately if a client has a bad experience in their care. Additionally, we recommend seeking clinicians who can provide you with a clearly articulated set of written ethical standards they endeavor to adhere to, whether those standards come from a professional organization or personal soul-searching.

Flight Plan

Create a "flight plan" and a safety plan collaboratively with your provider/s while sober, and review/update it before each medicine experience. Birth plans have become popular tool that birthing parents can use to a) educate themselves about the many choices that may emerge during labor and delivery, and b) communicate strategically with providers about their needs and preferences; we feel that structured advance planning for PAT sessions could provide similar benefits [298]. Here are some considerations you may wish to include in your flight plan if you feel you are at particularly high risk for AIT (link to assessment questions in section above), or otherwise have significant safety concerns:

- You may wish to have one or more support people present to serve as witnesses during your medicine session.
- You may even choose to delegate, "medical power of attorney" style, to allow trusted support people to make certain choices on your behalf while you are incapacitated by the medicine. If you pursue this possibility, it is important to have in-depth conversations with your support person and your clinician about what level of distress is appropriate for you to face, and what the likely outcomes of that distress may be—as well as having detailed discussions on the choices they are being entrusted to make.
- You may wish to arrange to have your session filmed, possibly even from a few angles, so that you have a lot of concrete evidence afterwards about what happened.

See "preparing for your session" section for more information on flight planning.

Cultishness

Keep an eye out for cultic group structures or dynamics. Accounts from the underground PAT world have described closed systems centered around charismatic leaders, exploitation of the labor of group members, and abundant use of what cult scholars call "thought terminating cliches" [23, 221]. Thought terminating cliches are phrases used to address cognitive dissonance while shutting down inquiry into the framework that produced that dissonance. For instance: members of the underground PAT community have told individuals who were assaulted during their therapy that they "called it in to themselves"—invoking a concept from new age spirituality, which suggests that people bring their life experiences onto themselves. In other words, survivors were told to stop considering the choices and volition of the human beings who betrayed them, and instead to focus on their own metaphysical complicity and potential growth that might emerge from their abuse. In contrast, in a non-cultic framework, people are allowed to ask questions and investigate what is under these "thought terminating cliches." They are allowed to disagree. They are not taught to believe they are dependent on just one source for healing. See appendix (NUMBER) for definitions of cults and lists of red flags and green flags to look out for, aggregated from the work of three different cult scholars.

Other Factors to Take Into Account

We think the conditions below increase the chances of lasting healing and reduce risk of [destabilization](#). While meeting all of them is not necessary for success, the more you have, the easier it will be. Many individuals with a history of trauma or mental illness have absorbed an "I have to do it all myself" or "these things were so long ago I should be over them already" attitude from difficult life circumstances, which makes it hard for them to feel they deserve supportive care. We hope this list will assist you in giving yourself credit for the difficulty of your endeavors, and help you give yourself permission to seek more support if that would be right for you. Consider these carefully when deciding what degree of professional guidance you need:

- Access to resources: Stable housing, financial security, stable healthy relationships, free time to process without compromising material stability, and friends or family skilled in emotional support.
- Understanding of healthy emotional behaviors (awareness of difficult moods and tools to manage them, conflict resolution, etc.).
- Impulse control
- Perseverance to navigate challenges in the healing process. Capacity to do between-session reconsolidation. Motivation to experiment with therapeutic methods to find what works for you.
- Time for and access to a secure and inviting space for your sessions, post-session rest, and reflection.

- Independence from those who have traumatized you, especially if they might react poorly to your insights and improvements. Most maladaptive schemas protected you at one point in your life. Dismantling these protections while you are still in a dangerous situation could carry risks and challenges.
- A habit of inquiring why you have the beliefs and behaviors you do. Acknowledgment that many of them are strongly influenced by psychological and social factors, particularly from early-childhood [43].
- Ability to identify dysregulation.
- Absence of severe mental health problems such as CPTSD, [attachment disorders](#), bipolar disorder, psychotic disorders, and personality disorders. We aren't aware of any high-quality research on how to predict destabilization, but we strongly suspect the trauma reactions we just listed are major factors. If we had to pick one scale you can rate yourself with we would suggest the Maladaptive Schema Scale by Buchanan et al. [46]. Unfortunately we aren't sure how to translate a specific score to specific recommendations on much good professional assistance is important for helping you in managing destabilization. The best we can recommend is using this as a vibe-check that you integrate with the other complexities of your personal situation.

3.4 **Dosing

Accurate dosing is important for efficacy and safety. The effects of MDMA are strongly dependent of dose and body mass [291]. The MDMA juxtaposition and maladaptive [schema](#) must also be close enough in strength to each other for [reconsolidation](#) to occur [85]. In traditional psychotherapy this generally succeeds without planning for this factor. However, we have noticed this is often regarded as not the case with MDMA therapy. Too low of a dose (0.75 mg/kg, for example) will likely not provide the safety and empathy needed for healing [29]. We have also observed that too high of a dose can cause the session to be so pleasurable that you're not able to engage with maladaptive schemas. This may feel good or produce highly valuable [non-dual](#) experiences that you can use later but is not usable for immediate reconsolidation. M. Liechti and Schmid [177] recommends an initial dose of 100mg for body mass less than 60kg (132lb) or those over 75 years old, and 125 mg for higher body mass ⁵. For those who need smaller or larger doses, anywhere from 75-200mg can be used. A 50mg booster dose taken after about 2 hours is often used to extend the productive duration of the session. Adjusting dosage in subsequent sessions may be helpful to reduce adverse effects, increase feelings of safety, or adjust for individual body chemistry. The effects of MDMA increase in response to increasing dose at a faster-than-linear rate because MDMA inhibits the enzymes that metabolize MDMA [71]. Because of this, we suggest increasing or decreasing dose in smaller increments than one would typically expect, especially at the

⁵MDMA is sold in hydrochloride salt form, and all stated masses are masses of the hydrochloride salt form [177]. MDMA is sold as a racemic (equal) mixture of the R-MDMA and S-MDMA enantiomers (a right or left handed version of a molecule), though it is possible to purify either enantiomer [289]. They have different effects.

upper end of typical dosage. Accurate data on the upper limit of safe doses is unfortunately absent due to difficulties translating the results of animal testing to humans [230].

Storage of MDMA is simple because temperature (Only temperatures up to 20°C or 68°F were tested.) and water do not affect its stability [57]. Measuring dosage is more difficult. High quality analysis of adulterants and dosage can only be done with sophisticated laboratory equipment. We have not vetted them, but are aware of two labs that offer international mail-in drug testing for adulterants and dosage: Kykeon Analytics [168] and Energy Control International [90]. Testing for adulterants and dosage at home is somewhat difficult and unreliable. It is possible to test for the presence of some, but certainly not all common adulterants using reagent kits like the one from DanceSafe [66] [67]. It is not possible to accurately verify the quantity or concentration of MDMA (or fillers, binding agents, and adulterants) at home. As far as we are aware, pills rarely specify how much MDMA they contain and it's always mixed with fillers and binders. Crystals are often, but not always pure MDMA. Some vendors will package measured and specified amounts of crystals into capsules as well. If you do obtain MDMA of known dosage, we suggest using volumetric dosing to break your sample into doses appropriate for therapy. We suggest aiming for a simple-to-remember concentration of 1mg MDMA/ml water. Just dissolve however many mg of MDMA you have in the same number of ml of water. It is much easier to measure a ml of water-based solution than a mg of powder. Tripsit [306] also offers a volumetric dosing calculator. Note that MDMA is extremely bitter [206].

When applying scientific studies to one's own life and health, it is important to remember that the data we glean from these studies flattens a wide variety of individual responses by combining them into readable averages. You as an individual may experience something very different from the average participant of any given study, and that may be totally normal and fine. Some examples include: you may be much more or less sensitive to the psychological or physical impacts of MDMA. The medicine may impact you for a greater or lesser amount of time than it impacts the average person. You may experience more healing, faster, than the average study participant, or you may not be helped by MDMA at all. Many normal human variations, like low or high body weight, recent pregnancy, or menstrual cycle status clearly have an impact on many mental health interventions (especially when it comes to effective dosage), but are not typically studied at all.

One of the great frustrations of mental healthcare research is that every real life situation is infinitely complex, and a corresponding infinity of confounding factors have the potential to influence outcomes. We encourage you to discuss with your clinician any difference in what you are experiencing (during any mental health intervention) from what the average response is that you might have expected from the research. It's important to both keep an eye on any health and safety concerns that might be related to your response, while also remembering that the range of normal and healthy responses to any mental health intervention is much broader than the averages suggest.

3.5 Dissociation and Avoidance During the Session

[Dissociation](#) and [avoidance](#) are challenges for MDMA-therapy, as they also are for traditional psychotherapy [245]. We group them together in this section because they both often inhibit

conscious experiences of contradiction, a requirement for [reconsolidation](#) [85, 166]. The various ways to deal with each problem are also similar. We list the common ones at the end of the section.

As described in Chapter 2.2, [immobility](#)'s core function is to reduce movement to such an extent that the predator who caught you loses interest and leaves you alone [166]. While immobility is biologically complex, its effects in large part derive from the brain producing opioids in response to a combination of powerlessness and threat (this is the typical activator, some people may dissociate in response to atypical activators). Of course, the [prediction](#) of threat and powerlessness during a therapy session is typically an over-generalized [schema](#) instead of actual threat of immanent death and powerlessness. Therefore, we hypothesize that reducing immobility requires at least one of:

- Reconsolidating the prediction of powerlessness and threat. We think some clinical experience indicates that MDMA can reconsolidate the originating predictions if immobility isn't too strong [245]. Higher doses may help with higher amounts of immobility. Razvi and Elfrink [245] reports consistent success reconsolidating (our interpretation) the activating schema for immobility by "...bringing blankness, flat affect, nothingness, boredom, sleepiness, or sobriety [the subjective effects of immobility or other dissociative states during [psychedelic-therapy](#) sessions] into focus." Further, "In a psychedelic-assisted session, it might take staying with it from minutes to a full day-long session, but it will crack."
- Sending signals of safety and/or power to your nervous system. The signals might not reconsolidate the originating schema, but they balance out the amount of threat and powerlessness that the nervous system perceives, or possibly deactivate the originating schema. MDMA may also conceivably do this, and higher doses may help more. Additional sources of safety may include: an attuned, skilled, and ethical therapist or guide whom you work well with, a comforting and safe physical environment, and sufficient pre-session preparation. We suspect mindfulness and [grounding](#) exercises operate via this mechanism. It may be easier to reconsolidate the schema triggering dissociation after the symptom is reduced.
- There is low quality evidence that 50-250mg of the opioid antagonist naltrexone inhibits opioid-mediated states (like immobility and [freezing](#)) with a moderate-large effect size [93]. Naloxone and nalmefene have similar mechanisms of action and could conceivably also work, though this hasn't been demonstrated. Naloxone's half life seems more appropriate to MDMA therapy than naltrexone's. Some of these medications require prescriptions in certain jurisdictions and collaboration with a prescribing medical professional may be necessary. We are not aware of any attempts at combining opioid antagonists with MDMA. If you try this novel combination, we suggest using lower doses, as all drugs have side effects, ranges of safe dosing, and interactions with other drugs, including potentially MDMA. RXList [259] provides thorough information about naltrexone. We are unable to provide instructions on safe and effective use here. Reducing dissociation may make reconsolidating the schemas triggering it easier.

Note that the original situation that created immobility-activating schemas likely also involved extreme levels of fear, anger, and [fight-or-flight](#) responses [166]. These will often be

felt after the immobility is reduced [245]. We recommend reviewing the list of immobility symptoms in 2.1 before your session. This may help you better identify immobility before if it occurs. We also recommend Razvi [244] for more information on the topic.

Freezing's function is to put a fight-or-flight response temporarily on hold in situations where the predator may not spot you if you stay very still [166]. It involves an opioid response, prediction of threat, and some other prediction (perhaps some type of uncertainty about the threat) or mechanism that we are not aware of that differentiates its activators from the activators of fight-or-flight. In the absence of knowing this other factor, we suggest the same interventions listed for immobility, but to only focus on safety instead of safety + power.

We aren't sure what specific predictions activate forms of dissociation that don't involve immobility and freezing. Threat is probably involved and you might be able to treat it similarly to freezing.

We define avoidance as consciously or unconsciously diverting attention from therapeutically important schemas. We think uncertainty about the process of tuning in to maladaptive schemas could also play a similar role. Most helpful techniques for either avoidance or uncertainty boil down to tuning in to whatever, possibly subtle, fear, anger, or other distress you are feeling in the present moment. The following may help with that:

- An attuned and skilled therapist or guide whom you work well with can help you notice your feelings.
- Looking at certain material (letters, photos, etc.) may more strongly activate schemas you want to work on.
- We think Razvi and Elfrink [245]'s [Selective Inhibition](#) is promising, though it hasn't gone through any controlled study. The original intention for the technique is for "unsticking" [defense cascade](#) activation during psychedelic therapy, but we think it may also be useful for addressing avoidance that doesn't involve intense defense cascade activation. Selective Inhibition consists of suppressing all movement and all escapist thoughts. This may result in less "noise" in your mind, making the active schema relatively louder and more noticeable. Any distressing emotions or physical sensations of distress (muscle tension, altered breathing patterns, etc.) are then payed attention to and will be reconsolidated.
- Mindfulness practices of being noticing and staying present with your experience may also help (see Brach [37] and Smookler [283]).

Mindfulness

Selective Inhibition

3.6 **Organizing Community Care

A significant and increasing body of work supports the effectiveness of peer support within the context of formal mental health services [274]. At the same time, some have called for a "reimagining" of peer support in order to take advantage of the unique (and perhaps

uniquely helpful) qualities of peer support, which reach outside of the conventional borders of professional mental health services [118]. It is this latter project to which we hope to contribute, offering strategies and framings drawn from our experiences organizing care on a mutual aid basis, outside of the formal mental health system. We have observed that individuals who are struggling with mental illness may be aware that having a strong support network might aid significantly in their recovery, but may also lack the skills or the mental framework to:

- Cultivate such a support network
- Confidently ask for help in a way that is appropriate to each relationship, relationally sustainable, and not manipulative or unduly high-pressure
- Recognize what specific tasks, activities, or forms of support that network might help them with

In this section, we will discuss each of these processes and suggest a variety of tools and resources which may or may not be empirically validated, but which we have found helpful in these tasks. Finally, we wish to acknowledge that for a wide variety of reasons, these strategies will not be accessible to everyone. We only hope that for some people, they increase access to sustaining connection and healthy relationships of mutual care.

Cultivating a Support Network

8% of Americans report that they don't have any close friends [119]. Fehr [105] identifies four components of friendship formation: environmental, individual, situational, and dyadic. This is Fehr's summary of the research of the research on these four factors (emphasis ours):

A necessary first step for the development of most friendships is that two people's paths must cross. This is more likely to occur if the two people live near one another (e.g., same neighborhood, same building, same floor, same room) than if they do not. Living in a city or, more important, sharing the same work or school **environment** also increases the likelihood of contact. People who know people also are more likely to become friends. The probability that two individuals will meet increases to the extent that their social networks overlap.

Once two people meet, whether or not they decide to pursue a friendship depends on several additional factors. At the **individual** level, each scrutinizes the other for evidence of disliked qualities or other characteristics that may make him or her unsuitable as a friend. If these exclusion tests are passed, then inclusion tests will follow. It is likely that a friendship will be sought if each perceives the other as attractive, socially skilled, responsive, not shy, and if the two people are similar in a variety of ways.

If both exclusion and inclusion tests are passed, one might think that a friendship would be inevitable. However, **situational** factors influence whether or not a friendship actually is formed. Research on these factors suggests that two people are more likely to develop a friendship if they anticipate ongoing interactions, if they are dependent on one another, if they see one another frequently, and if each person's "friendship dance card" still has some

room on it. Finally, the likelihood of friendship formation depends on **dyadic** variables such as whether the two people like one another and whether there is an appropriate sequencing of the depth and breadth of self-disclosure [105, p. 68].”

In deference to this research—but also from our own experience—we feel that for maximal likelihood of success in building new friendships, one must routinely put oneself in environmental and situational contexts that are conducive to friendship formation. That means contexts that:

- Put you in repeated proximity with people you feel you have something in common with, at least some of whom are likely to have resources to spend on a new connection
- Allow for plenty of friendly, cooperative interactions
- Provide a reasonably pleasant/low stress environment, at least some of the time

Here are some ideas for contexts that may meet enough of these criteria to facilitate friend-finding success:

- A workplace or school (ideally in person)—especially effective if full time and/or residential
- A meditation group, synagogue, or church congregation
- Gyms, pools, dance/martial arts/yoga/pilates studios, and rec-centers
- Recurring dance nights (salsa, blues, contra, etc.) or jam sessions at various venues
- Events, clubs, or groups you find through local newsletters and event calendars
- Events through your public library, senior center, community center, game shop, or farmer’s market
- Night classes through a community college—may focus on art, craft, or trade, or hobby related skills
- Civic engagement with local government and/or activist groups
- Long distance hiking adventures known as “through hikes” on the Appalachian Trail or others
- Volunteering (animal shelter, horse rehab stable, soup kitchen, nonprofit thrift store, etc.)
- Therapeutic support or self-help groups, such as Buried in Treasures groups or Alanon
- Festivals, fairs, and conventions—the intense collaboration involved in festivals like burning man [286] and Pennsic have been known to facilitate friendship formation in a way that is difficult to replicate in the atomized mundane working world of midlife in the USA.

- Online services like meetup.com, Bumble BFF, Captain Awkward meetups, or Buy Nothing groups, which connect people for offline interactions

Some online games or social networking sites can facilitate friendship formation for some users. We recognize that online socializing offers massive accessibility advantages, and we have hope that in the future digital spaces will be designed to facilitate healthy friendship formation [124] rather than being designed to extract the maximum amount of data, time, and/or money from participants. For the time being, online socializing is fraught with problematic ethical and mental health impacts—while also providing benefits, including connections that may be indispensable [61, 160, 227, 235]. It may be that the collaborative activities of gaming or the creativity of posting are more satisfying or helpful for you than reading and reacting to others’ posts, and it may be that some games leave you feeling better (or support you in interacting with others in a more satisfying way) than others. In light of these complexities, we recommend checking in with yourself carefully to gather data about how you actually feel before, during, and after specific online activities. We also recommend using whatever executive function supports are necessary to limit your participation in activities that you don’t find helpful.

If you are able to repeatedly and/or protractedly place yourself in a context (environment and situation, in Fehr’s framework) which offers you a good chance at proximity with high likelihood potential friends, you will still have the individual and dyadic factors to sort out. Let’s return to Fehr’s account of individual factors—individuals are looking for someone who is “attractive, socially skilled, responsive, not shy, and if the two people are similar”. We will leave the question of attractiveness to the myriad other texts and resources on the topic, other than to point out that the research does suggest that social skills and attractiveness may represent two separate routes to friendship—you don’t necessarily need both ⁶—and that attractiveness is relative to context [116, 174, 184, 204, 217].

Fehr identifies the important social skills for friendship formation as initiation (more important in the early finding/making friends stage) and self-disclosure (important for moving from an acquaintanceship to a friendships, and increasingly important as friendships deepen.) Other research suggests that responsiveness (including nonverbal responsiveness) and assertiveness are also important social skills for creating and sustaining satisfying friendships [248].

To work on initiation skills (how to introduce yourself and make a good first impression) we recommend the content and coaching services from Healthy Gamer and advice from Captain Awkward. For folks who feel this would be a reasonable choice for them, we also recommend setting "getting rejected" as a positive goal, as a kind of prolonged exposure

⁶There is clear data that social skills correlate with social support [262] and also that attractiveness and social skills represent two separate routes to friendship for women [246]. For men the data is less clear—apparently for men, social skills and attractiveness, though still both separately impacting social success, tend to be highly correlated. Since social skills can be taught [39, 265], we feel this raises interesting questions about how men are socialized. Research on the correlations between attractiveness, social success, and social skills in nonbinary people has not yet been published. Despite these complexities, we strongly recommend social skill development as a path to greater social success for all genders. For anyone who is a man or a nonbinary person or who is close to a man or nonbinary person, we recommend Brené Brown’s workshop *Men Women and Worthiness* (<https://www.soundstrue.com/products/men-women-and-worthiness>) as a valuable exploration of gendered challenges in socialization, self disclosure, and life.

practice to desensitize yourself to the downsides of rejection. Finally, we have observed that in some cases, increased confidence in one's "appropriate self-disclosure" skills can make initiation more accessible.

Our recommended resources for learning appropriate self-disclosure skills are the ladder of bids (See Gottman [122], Chapter "How Couples Build Trust With Attunement"), along with B. Brown [42] work on "Shame webs vs support networks." We have witnessed considerable transformation in these skills by motivated individuals who practiced applying these tools over time.

We feel that assertiveness and nonverbal responsiveness are probably best addressed by cultivating a mindset of confidence, compassion, calm, and balanced entitlement, and trying to carry this perspective into social interactions. We recognize that this is extremely hard to do when one is mentally ill—as, indeed, are the recommendations in this section generally. To cultivate this positive mindset, we recommend the following resources (if you find them helpful and resonant to your own situation):

- The work of Brené Brown generally
- *Good Inside* by Dr. Becky Kennedy (putatively about parenting, but the general concepts can be applied to relationships with self and others generally). See Appendix [A](#).
- *Grit* by Angela Duckworth
- *Bird by Bird*, by Anne Lamott
- *The Upside of Stress*, by Kelly McGonnigal
- How to live alone and like it (every ism, but very good at teaching people to "romanticize your life"—to tell yourself and others a positive and appealing story about yourself and how you live—and breaking this down into many specific sub-skills and practices)
- Compassion meditation
- Other mantras ("it's OK to make mistakes", "I am enough/I have enough", "I am becoming consistently capable of lovingly attentive behavior")
- The unwinding anxiety app

We are sure there are many other resources that would also serve this purpose well. In addition, despite the inherent awkwardness and discomfort of this practice, we would expect role playing with a therapist, coach, or reasonably skilled peer to be an excellent strategy for improving any of these social skills.

3.7 **Pre-Session Preparation

Proper planning of a session is important for comfort, safety, and success. This is traditionally divided into three sections of mindset, setting, and cultural/personal matrix [87]. We

add two more: tools for the session and planning for the post-session. The concept of "set and setting" or the "set/setting/matrix" is a popular framework for understanding, within [psychedelic](#) subcultures, what leads to a "good trip" or "bad trip" [87]."

Mental Preparation and Expectations (Mindset):

- We suggest journaling about the things, places, practices, people, or situations with whom you feel safe and at home, and with whom you feel unsafe. Then make a diagram with two axes, safe-feeling and accessibility. Plot at least the top 10 items you journaled about on this diagram. Identify the items that are both safe and accessible and keep them in mind for possible post session [destabilization](#). We suggest planning increased time with the safe items and decreased time with the unsafe items in the days and weeks following your session.
- If you hope to use your neuroplastic period to develop practical new habits or to reconnect to a project that you've been feeling too overwhelmed to engage with, we recommend doing some "habit mapping (see Brewer [38])." This consists of identifying behaviors you are hoping to adjust, identifying what triggers lead you to engage in those behaviors, and identifying what results emerge after you engage in the behavior. For example, I might identify that I would like to adjust the habit of scrolling through social media on my phone for three to five hours every day as soon as I get off of work. Identifying triggers might involve exploring: what are the feelings that precede my going online? What are the stories I tell myself? What physical and social environment am I experiencing that supports this behavior? Am I triggered by loneliness, by a desire to be free of demands for a period of time, or by a feeling of boredom/desire for stimulation—or all of the above? What happens when I work the second half of my workday in a communal space, vs when I work alone? What happens when I lock the phone in the glove compartment of my car during my lunch break, and don't revisit it until I've walked outside to the parking lot? The last stage of habit mapping involves checking in with yourself and taking time to feel *all* the consequences of enacting the habit. It might be that you feel stiff and sedentary, which feels bad in your body; it might be that you find yourself feeling anxious or tired or lonelier than when you started scrolling, or that you get caught up in cycles of self-judgment or shame about the behavior. Maybe you feel frustrated and wish you had more time for other things. Or maybe you feel some of these things, and also feel delighted and inspired by the content you are consuming. Generally, the goal of habit mapping is to observe and record the landscape of each habit as it plays out in your life, and to truly open yourself to understanding on a deep level whether the choices you are making are the choices that are best for you. In the context of preparing mentally for memory [reconsolidation](#), taking some significant time to sit with whatever it is that you feel an intense need to numb (and sitting with the consequences you are willing to face in order to achieve that numbing) may prime you to be able to face that thing during your medicine experience.
- Thought records are an excellent mental health and memory reconsolidation tool that can be used alone or with a clinician. We recommend completing at least one prior to

your first medicine session, to familiarize yourself with the process and support yourself in making optimal use of this tool afterwards, during your neuroplasticity period. See Harper [132] for a worksheet.

- Shame mapping can help you identify many core [schemas](#) to address during the session. See Appendix B for details.
- [Dissociation](#) and [resistance](#) are the primary obstacles to healing during a session. Learning about the signs of these beforehand could help you recognize and deal with them during the session. Refer to Section 3.5.
- Set an intention to face and stay present with whatever fears, anxieties, anger, grief, etc. come up, without [avoidance](#) or distraction. This is necessary for reconsolidation [85]. Writing down the challenges or emotional difficulties you would like to address during the session can be helpful for bringing these schemas into awareness during the session. However, be cautious about schema-specific expectations about what you want out of the session, how you think it should go, or what you will learn. These expectations often do not match up with reality and can become ways to avoid reconsolidating the maladaptive schemas that are actually present. We think an established practice of loving-kindness (Kabat-Zinn [156]) or focus meditation (Brach [37]) may help you apply these techniques to your own distress during the session and help you stay present with distress. Additionally, we suggest intending to view the truth of the schema's beliefs or emotional reactions with agnosticism, something like "this belief and emotional reaction may or may not be true or helpful; I will stay present with it to learn why the schema exists and how it influenced me."
- Catch up on sleep. Therapy requires focus and energy. MDMA promotes focus and energy as well, but we suspect it can only help so much if sleep is lacking.
- Wondering how other people describe their sessions? We suggest reading the top posts here for a survey of how successful MDMA therapy can feel: [r/mdmaththerapy](#). The top posts mostly describe productive sessions that don't contain unworkable dissociation or avoidance, or poorly handled destabilization. Sorting by "new" will also show descriptions of less productive or more disruptive sessions. Godes et al. [120] also lists the common self-reported subjective experiences of MDMA-therapy clients: "Staying with what 'is'; decreased reactivity; insight, reflection, linking; mental clarity; recovery of [traumatic](#) memories; disentangling trauma from self; reuniting lost affects and parts; self-acceptance; joy, happiness, gratitude; hope and empowerment; relaxation, calmness, peace; comfort; gratitude, empathy, compassion; union, wider perspective; inner healing intelligence [the therapeutic framework used in this study]; accessibility to emotions; mind-body connection" The paper has full descriptions of these items.

Setting:

- MDMA's stimulant effect may prevent sleep if the session is started later in the day, so we recommend starting in the morning [31].

- Eating is avoided if possible on the morning of the session because some people experience nausea [64]. Taking medicine with food can also delay onset of effect. M. Liechti and Schmid [177] provides (prescription) medication recommendations for nausea.
- Significant distraction during the session likely reduces efficacy [254]. It is helpful to arrange easy access to necessities like a restroom, snacks, and water.
- MDMA commonly causes mild hyponatremia (low plasma sodium concentration) in individuals who drink fluid during the session, though not in those who don't drink anything [22]. We suggest adding a bit of salt to anything you drink. If your environment is hot enough to cause sweating during the session (MDMA can further increase sweating. [64]), replacing fluids and sodium will become more important to avoid dangerous heat illness (MDMA further raises body temperature by 0.2-0.8°C or 0.4-1.4°F[178]) and severe hyponatremia.
- Prepare your environment or travel somewhere to maximize your feelings of comfort and safety. These could add to the feeling of safety from the medicine and ease down dissociation and resistance and increase mismatch. We propose that carefully expanding your session environment could be beneficial once you are experienced with the medicine. For example, if you have trauma from dogs, you could safely activate that schema by petting a dog who you know won't act aggressively, and who's human is nearby to manage them if you feel like the experience is too much to handle.
- Solitude, except for a trusted and experienced guide, therapist, or sitter, promotes inward-focus. A sitter can help with logistics, listen to your feelings, or handle mundane events like someone knocking at the door [295]. Sitters should possess trustworthiness, presence (ability to listen to your distress without becoming distressed themselves), and empathy. Interacting with strangers may cause problems if they do not understand what is happening.
- Pets may be a source of comfort and safety, but shouldn't be distracting.

3.7.1 Cultural/Personal Matrix:

Unfortunately, the researcher who originated the term "matrix" was credibly accused of such intense abuse—particularly in the realm of crafting abusive environments and mind-sets in those she treated—that we feel her advice on this front must be presented with the context of those allegations foremost [69]. This is despite the fact that this framework, as published, look helpful to us from afar. As such, we encourage you to critically engage with this framework if it appeals to you, and, if you are using it, to pay special care to boundaries, power dynamics, supervision, and other safety mechanisms to avoid misconduct and abuse. Eisner [87] defines matrix as the "...environment (1) from which an individual comes, (2) in which the individual lives during the time of the sessions, and (3) to which the individual returns after successful therapy—the everyday living space..." This is important because "Rapid change is very difficult to sustain if the living environment is the same as the one which caused the difficulties in the first place." Family, living situation, and culture

have complex interactions with the process of MDMA therapy. In some cultures, like those where ayahuasca use is currently endemic in certain areas of South America, knowledge of psychedelics may be widespread and their use accepted. Finding help in dealing with certain after-effects may be much easier in those contexts. Other social or family contexts can be hostile or counterproductive to the process of MDMA therapy.

Tools:

- We've heard that some people like to self-narrate the session and record the audio with their phone. Listening to it later may aid further reconsolidation and insight.
- Eye shades and noise-cancelling headphones can reduce distractions.
- MDMA can cause jaw clenching and headaches [179, 212]. Some people use mouth guards or pacifiers to reduce this effect or protect their teeth [89]. Over-the-counter pain relievers may help after the session. Those with jaw problems could conceivably need to take extra precautions or start with lower doses.
- The Fireside Project offers a hot-line to help people through challenging psychedelic experiences at +1 (623) 473-7433 in the United States [107]. Consider putting this number in your phone as an additional layer of safety.

Planning for After the Session:

- People often feel fatigued for 1-3 days after the session [179]. Prepping food and a comfortable place to rest in advance may be nice.
- Additional reconsolidation may be easier for a period of time following a session if that session helped you temporarily jump out of a set of self-reinforcing schemas that for one reason or another inhibited therapy. If it works this way for you it may be helpful to plan for extra reconsolidation efforts in this period of time.
- We suggest making a plan to try different techniques on subsequent sessions if you're worried that this first MDMA session might not work and is your only hope for healing.
- High quality sleep of sufficient duration is likely important for reconsolidation [278]. We suggest a highly effective evidence-based protocol called *Cognitive Behavioral Therapy for Insomnia* if you struggle getting quality sleep. Stanford Medicine has a guide [287].
- It may also be possible to use habit mapping (see 3.7) to guide you in crafting optimal support for your neuroplasticity period. For instance, if my after-work scrolling habit is driven by loneliness, I might arrange to volunteer at an animal shelter on certain days, and to have friends call and talk to me on other days—even if it's just for long enough to get myself started on a different self-care activity.

Chapter 4

Session and Afterwards

4.1 The MDMA Therapy Session

**The effects of a single MDMA dose are generally noticeable 30 min after taking the medicine, peak an hour after than, then last a further 3 hours [317]. Those with genetically low CYP2D6 metabolic capacity reach peak earlier [268]. A 50mg booster dose taken around hour 2 is often used to extend the productive duration of the session [177]. We warn you not to take more MDMA during a session than you initially planned to, unless you took a low dose and after 1.5 hours decide bumping it up to the equivalent of a regular dose would be better. It may help to not even keep any MDMA within easy access of your session location. Desires to take more are often due to anxiety about the session not feeling like what you expected or the feeling like the medicine isn't working, and can lead to increased adverse effects [45]. We suggest that anxiety about the session not working is actually a useful [reconsolidation](#) target, and staying present with "feeling nothing" may eventually resolve that issue. Food delays onset of effects [213]. We divide the session into traditional phases based on subjective effects and therapeutic potential:

**You may feel the following effects [179]: difficulty concentrating, jaw clenching, lack of appetite, dry mouth, impaired balance, restless legs, sensitivity to cold, restlessness, palpitations, restlessness, being cold, sweating, forgetfulness, heavy legs, weakness, hot flushes, tremor, paresthesia (a feeling of tingling or pricking), inner tension, brooding, nausea, lack of energy, exhaustibility, frequent urge to urinate, anxiety, and irritability. These were found in individuals who were not mentally ill, so while they could have been engaging with some maladaptive [schemas](#), most of this is likely due to the MDMA itself rather than [defense cascade](#) activation. You may experience closed-eye visual scenes (possibly of [traumatic](#) material) [179]. Colcott et al. [64] also reported non-cardiac chest pain/discomfort. In the absence of MDMA-specific advice, the cardiologist Nicole Bhavé, M.D. offers this general advice for what type of chest pain you should go to the emergency room for [113]:

...it most often boils down to the severity of the pain and the heart attack symptoms we mentioned above. If the pain is so severe that you feel like you can't function, or if you are experiencing central or left-sided chest pain — especially if you have nausea or a cold and clammy feeling alongside it — it is always safest to go to the emergency room. With chest pain, it's best to be cautious.

****Come-up**

The effects of MDMA become noticeable, but you are not yet engaging with the memories you want to work on. Some users experience anxiety [140]. We speculate this might be misinterpretation of MDMA's stimulant effects as anxiety, early engagement with distressing schemas, or fears about the session.

Peak

**Reconsolidation is possible here. Connection and safety become pronounced, though you may not notice this if you immediately engage with distressing schemas or are [dissociating](#).

**We believe the main goal here is emotional activation ¹ of your maladaptive schemas, a prerequisite for reconsolidation [85]. We've observed that once you're emotionally engaged and aren't distracted, the MDMA will reconsolidate the schema without any further effort. Because of this, we don't think therapeutic exercises designed to facilitate reconsolidation (e.g. coherence therapy or internal family systems therapy) will add any value.

**There are a number of ways to activate your maladaptive schemas:

- One may already be activated. We think this is the case if you feel any anxiety (even anxiety about the session not going well), fear, anger, or sadness.
- Looking at or listening to triggering material like photographs, letters, voicemails, etc.
- Just thinking about your issue, or telling your sitter, guide, or therapist about your issue.
- Talking with your partner about a conflict in your relationship or an insecurity you have about your relationship [63].

It is well-known that over-attachment to a specific therapeutic goal can be an impediment to progress because 1) reconsolidating certain schemas often seems to depend on reconsolidating some other schema (sometimes one you are unaware of) first and 2) people sometimes have inaccurate beliefs about what their issues are. Because of this, we suggest that if you don't feel like you are clearly activating (The type of maladaptive schemas addressed in therapy contain strong emotions, so the activation will be emotional [85]. Intellectualizing about the topic isn't sufficient.) and staying present with your desired schema, you should try gently noticing and focusing on any fear, anger, grief, anxiety, discomfort, or tension in your body or field of awareness. Once you've found one of those, stay present with it and it will reconsolidate.

*If you feel like you're experiencing profound ok-ness and self-love for the first time, or are seeing how trauma and the world works, we suggest feeling it fully and not worrying

¹Some people think getting insight is the primary goal during MDMA-therapy, but we disagree. Insight is important for conventional psychotherapy where you need to know what the schema is before you can reconsolidate it [85]. We don't think this is important in MDMA-therapy, where you can skip straight to reconsolidation without knowing what the schema is first. In our experience, insight is easier to come by post-reconsolidation, which can be accomplished after the session. This reserves scarce session time for difficult reconsolidation.

about anything else. We have observed (1 data point) that you can later use (with extensive practice) this knowledge of deep inner wellbeing to [mismatch](#) almost any maladaptive schema without the need for MDMA. We think that ability is enormously useful. See Section 4.5 for instructions. This experience is also a view of the end goal (regular life will never be total bliss, but it does point you in the right direction) of therapy, which can be a great motivator for staying on the healing journey long-term through challenges. The peace and compassion may not last long after this first session, but you will gradually get it much of it back as you reconsolidate various maladaptive schemas over the long-term [101]. If you find yourself repeating this experience on subsequent sessions, we suggest focusing on engagement with your target schemas. If the repeat experiences don't impart additional, new knowledge of ok-ness, we think they are likely not of therapeutic use.

Activating and feeling the emotions of the target schema is necessary to enable reconsolidation [84]². We think of it as focus-meditation, where you hold the feeling or belief of the schema in focus and gently dismiss distracting thoughts about, for instance, how beautiful the trees are. This can be deeply uncomfortable, but in our experience the MDMA almost always makes it bearable. The discomfort will be temporary; MDMA-induced reconsolidation will dissipate it over 10's of minutes. Insightful thoughts about how trauma impacted you or insights into human behavior may arise. Spend time on them if they feel cathartic or important. Leave them until after the session if they don't feel cathartic or important, reserving limited session time for reconsolidation or new experiences of profound wellbeing. It may also help to hold the schema with compassionate curiosity and agnosticism with regard to its truth. We have observed that activating and feeling the emotions of maladaptive schemas is a necessary part of MDMA-therapy. Thinking can be useful, but only if it occurs in conjunction with feeling. Thinking by itself is a waste.

*In our experience, your thoughts are also a reliable indicator of where in the reconsolidation process you are. Your thoughts often revolve around strongly activated schemas. For example, if your schema involves fear and a belief that you're dying, you may find your thoughts saying things like "I'm dying", "I'm afraid", "Death is horrible", "How could that person be comfortable with the thought of eventual death?", "Hospice facilities are scary", etc. Those thoughts will likely feel compelling. When reconsolidation finishes, those thoughts become less compelling or may shift into compassion for yourself or others. You can watch as your beliefs shift too. During a PTSD schema activation, you may believe to some extent (often vocalized in your inner monologue), for example, that you're being attacked. As that schema reconsolidates, you can see how that belief dissolves and you realize you're not actually being attacked. Sometimes our beliefs may stay the same while the emotional valence (positive, neutral, or negative) shifts. For example, you may have had anxiety about the thought of dying later in life. After reconsolidation you still know you will die, but it will no longer be distressing³.

**If you feel "...blankness, flat affect, nothingness, boredom, sleepiness, or sobriety..." you're probably dissociating [245]. Focus on that nothingness while suppressing movement,

²Emotional activation is necessary because the schemas addressed in therapy almost always involve strong emotions. One can reconsolidate schemas that don't involve emotion without emotional activation.

³It could also be that the belief that feels like it stayed the same is not the schema you actually reconsolidated. It might be that a second, unnoticed schema, like "death is bad" was reconsolidated and that belief actually dissipated.

thought, and [avoidance](#), and "...it might take staying with it from minutes to a full day-long session, but it [the dissociation] will crack." Note that you may transition from dissociation to [fight-or-flight](#), which is challenging in a different way. Refer to Section [3.5](#) for more information.

You may feel what is called [resistance](#). This can be a few things: simple avoidance of emotional pain because it is uncomfortable; beliefs that say confronting/healing emotions is bad; or beliefs of an activated schema that say their protective function is very important and you shouldn't let that go. While the protective function of these schemas was important at one point, it has become an impediment. If you can do it, we suggest focusing on any resistance schemas first. Reconsolidating this will make the rest of your therapeutic efforts much easier, as you won't have to fight against a part of mind telling you to stop what you're doing. If you feel uncomfortable assuming the resistance is maladaptive, you can approach the truth of the schema's beliefs or emotional responses with agnosticism, "It may or may not be true or helpful; I will stay present with the feeling to learn why the schema exists and how it influences me." If you can't focus on the resistance schema and another schema is taking precedence, that's ok. You can revisit the resistance later.

If you panic, focusing on that feeling or just hanging-on will often reconsolidate it. Trying to avoid distress through distraction will likely just prolong it by impairing mismatch. We suggest calling the Fireside Project hotline at [+1 \(623\) 473-7433](#) if you feel like you need help. [\[107\]](#). If you're having intense thoughts of, or are planning suicide, call .

****People can only do so much (2 hours for MG) reconsolidation in a day before they become emotionally exhausted. This is commonly called therapy hangover, though therapy hangover on MDMA may not feel like regular psychotherapy hangover because the drug effects are mixed in. As far as we can tell, the phenomena hasn't been scientifically studied. We semi-educatedly speculate that it involves neurotransmitter depletion, limits on the neural protein-synthesis and gene expression pathways fundamental to memory reconsolidation, other limits on synapse formation, or the after-effects of high levels of stress hormones. We've observed that it dissipates within a day or two.**

****Come-down**

You may still feel high, but engaging with painful emotions is more difficult and reconsolidation may no longer be achievable. We've observed that this phase can be difficult for some people.

****After-effects**

Trace effects are usually felt for longer, occasionally up to 3 days [\[179\]](#). The concentration of MDMA in the body decreases by half every 8.5 hours in those with average liver function [\[70\]](#), though some effects dissipate at a faster rate due to rapidly-developed tolerance [\[102, 229\]](#). You may feel the following effects (Mostly the same effects as felt during the session. Fatigue, headache and insomnia are notably present here but not common during a session.) [\[179\]](#): difficulty concentrating, jaw clenching, lack of appetite, dry mouth, impaired balance, restless legs, sensitivity to cold, restlessness, palpitations, restlessness, being cold, sweating, forgetfulness, heavy legs, fatigue, weakness, hot flushes, tremor, inner tension, brooding, lack

of energy, exhaustibility, frequent urge to urinate, headache, insomnia, irritability, and bad dreams. These were found in individuals who were not mentally ill, so while they could have been engaging with some maladaptive schemas, most of this is likely due to the MDMA itself rather than defense cascade activation.

4.2 ****Troubleshooting**

Sleepiness, disconnection, or heaviness

MDMA is a strong stimulant and generally increases feelings of energy [317]. Activating (perhaps unconsciously) [schemas](#) of powerlessness and threat during therapy commonly increases [dissociation](#), which can include sleepiness [166]. We suggest dissociation is the most likely cause for sleepiness during a session, through atypical responses to the medication or other medical conditions could conceivably play a role. See Section 3.5 for suggestions on working with dissociation. We suggest following the dissociation guidelines first even if you suspect an atypical stimulant/neurotransmitter response because these conditions may be difficult to distinguish. There is a list of dissociation symptoms that may prove helpful in differentiating dissociation from another response in 2.1.

Not Feeling Anything or Feeling "Meh"

- Your expectation for the session may not match up with the maladaptive schemas actually present and in need of [reconsolidation](#). This can present as disappointment or anxiety about the trip itself. This disappointment or anxiety is the key feeling to focus on and work with.
- We suggest you may be inadvertently avoiding an unnoticed feeling ([avoidance](#), [resistance](#), or dissociation). Practicing different types of meditation (see Brach [37] and Smookler [283]) for 30 minutes can often help you notice and engage with subtle feelings.
- Long-term use of reuptake-inhibitor antidepressants blunts the effects of MDMA [103]. This effect may persist for multiple months after discontinuing these medicines.
- The dose may have been too low [29]. See Section 3.4.
- The substance might have been something other than MDMA [261]. Testing can prevent this problem.
- Some medicines work very differently with some individuals' body chemistries. We have observed that some people who think that MDMA might not work with their brain were actually experiencing dissociation or avoiding an anxiety they didn't identify as a reconsolidation target. We suggest working through Section 3.5 before concluding that MDMA doesn't work with your brain.

Engaging with Feelings that are too Overwhelming to Stay Present with or Reconsolidate

A higher dose on the next session could provide enough additional safety to engage with these emotions. Keep in mind that because MDMA inhibits the metabolism of MDMA, effects increase more-than-linearly with dose [71]. See Section 3.4 for more information. Alternatively, a trusted sitter, guide, or therapist could help provide an additional feeling of safety.

Feeling Great but no Durable Therapeutic Effect

Reconsolidation requires the positive [mismatch](#) and maladaptive schema to be close enough to each other in strength [85]. The MDMA dose may have been too high for you. Alternatively, looking at photos or messages that remind you of the schema you want to work on could increase the strength of the maladaptive schema.

Feeling Certain New or Heightened Adverse Effects up to 3 Days After a Session

[Post-reconsolidation exhaustion](#) is common and temporary. In our experience, MDMA-therapy may facilitate extraordinary amounts of reconsolidation, and thus extraordinary amounts of exhaustion. MDMA itself also frequently causes a variety of side effects (See Section 4.1). These symptoms are strongly correlated with dose and can last up to 3 days [179]. If symptoms extend beyond 3 days, we suggest this may be a symptom of a schema you uncovered during the session, or conceivably a rare medical problem. See the next subsection in this case.

New or Heightened Adverse Symptoms Lasting more than 3 days After a Session

[Trauma](#) therapy often follows a pattern of feeling worse before it feels better. You will notice previously hidden distressing schemas as some schemas are healed, and avoidance and dissociation are reduced. This is uncomfortable and distressing emotional memories can have a wide variety of mental and physical symptoms (see 2.1 for a list of [defense cascade](#) symptoms) [139, 167]. Continuing with reconsolidation will reduce the backlog of distressing schemas. Sometimes you need to develop symptom management skills or resources to manage the immediate problem, as detailed in Section 4.9. If you seek medical assessment, it is beneficial to find a medical professional who understands the physical and psychological symptoms of trauma. It would be ideal to find a medical professional who will anticipate and accommodate your trauma-related safety needs, or at least be willing to listen and adapt. Unfortunately, the United States currently has a severely over-stressed medical system where medical professionals are frequently both undertrained on these topics and lacking the skills to effectively implement the understanding they do have. Additionally, many under-supported healthcare professionals are arguably undergoing extended workplace trauma themselves, which does

not necessarily lend itself to optimal participant care. As such, we recommend taking a posture of firmly compassionate self-advocacy wherever possible. You deserve safe and trauma informed care; whether you receive this care or not is not a reflection of what you deserve. You may wish to take notes about the symptoms you are experiencing or collect data (like the safety section of this document) about the safety of MDMA to bring with you to your medical appointment; these measures can help you support your healthcare professionals in giving you the best quality of care possible.

For a strong basic education on [psychogenic](#) physical illness, with an emphasis on the understanding most needed from a participant's perspective, we recommend the video [You're Not Crazy For Being Sick - Understanding Psychosomatic Illness](#).

Evans [95] has recommended the following organizations offering support for challenging experiences and adverse effects. We have not vetted the list, but we generally recommend specialist services such as these over a non-specialist psychiatrist or doctor who likely doesn't understand what you're going through and may misdiagnose you. Most of these groups offer service to anyone anywhere in the world.

- The [Psychedelic](#) Substance Outpatient Clinic at Alexianer St. Hedwig Hospital [11].
- The Challenging Psychedelic Experiences Project has information and an online peer support group [299].
- ICEERS has free integration services for challenging experiences [149].
- Cheetah House may be able to help via online consultations [53]. There is a lot of overlap between the adverse effects of meditation and psychedelics.
- The Ecstatic Integration Substack contains a wealth of information on adverse effects [98].
- The SHINE Collective offers support groups for those who are abused while on psychedelics, by psychedelic practitioners, or in psychedelic spaces [276].
- PsyAware is planning to offer support services for challenging experiences, abuse, and other transgressions [237].
- The Psychedelic Experience Clinic offers therapy for challenging experiences [300].
- John Hopkins Personalized Psychiatry has knowledge of psychedelic side effects [152]. Email Dr. Bekhrad at abekhrai@jhmi.edu to set up an appointment.

Feeling Good for a Few Weeks After the Session but then the Symptoms Come Back

We don't know what this phenomena is. A few weeks roughly equals the length of time of a certain type of increased neuroplasticity that Nardou et al. [218] found following a MDMA sessions in mice. However, that lab's results with psilocybin have failed to replicate, calling their MDMA results into question too [187]. It could be that something about your

MDMA session or your expectations about MDMA-therapy temporarily deactivated the set of schemas that cause your problems. Perhaps one schema of a set of self-reinforcing schemas deactivated, and then the whole network of self-reinforcing schemas deactivated. Those schemas may eventually re-activate in the presence of their regular triggers if they are not reconsolidated.

Discomfort Revolving Around the Nature of Self or Existence

A variety of life experiences—particularly psychedelic experiences and meditation—can induce shifts or insights about one’s sense of self that are not easily integrated with the default human model of world and self [99]. While these insights can feel profound, and are sometimes true or healthy, we suggest applying some skepticism because psychedelic experiences can incite a variety of mutually exclusive beliefs (e.g. metaphysical dualism vs. idealism [302] and amplify feelings of meaning [136].

Many contemplative traditions (historically, mostly in religious contexts) frame certain existential insights—such as unity with God or [non-duality](#)—as important, positive, and potentially [destabilizing](#) [150]. Those traditions often frame some challenging experiences as temporary (when properly handled) periods in the longer path of contemplative development—as legitimate parts of the process. Some other challenging experiences may not be considered part of the process. As Lindahl et al. [181] discuss, "...what is categorized as 'progress' versus 'pathology' may differ across traditions, lineages, or even teachers." If the existentially disruptive experience you had is accurate to your most honest perceptions of the world and yourself, we think you will not be able to fully return to your prior schemas (and their attendant adaptations and behaviors) without any continued disruption from the new schemas (and *their* attendant adaptations and behaviors). Deliberate attention to the insight and its implications in daily life will facilitate high levels of integration of the new insight, whereas avoidance will tend to keep the insight poorly integrated. We also think that, as in healthy therapeutic relationships, your practice of integration should align with your goals and expectations—that your therapeutic practices should be in pursuit of what is right for you, coming from your own self-determinative autonomy. This alignment is a predictor of whether you will see challenging experiences as positive or negative [181]. Regardless of how you proceed, the most important thing is stabilization of adverse symptoms if they are overwhelming or preventing you from accomplishing critically important tasks in your life. Cheetah House [53] specializes in helping people through the stabilization process. In addition, many practices aiming toward high levels of integration of unitive or non-dual insights may involve processing large amounts of existential distress [150] that can be destabilizing, especially when done without proper practice or supportive teachers that respect your autonomy and goals [181]. This may be difficult when mixed with mental illness, or it may be that existential distress is already intertwined with your mental illness in such a way that they can only be processed at the same time. The book *Trauma-Sensitive Mindfulness* by David Treleaven focuses heavily on ways of engaging with mindfulness practices that are fully respectful of autonomy, and we recommend it [304].

Below are several resources that many have found helpful; we do not specifically endorse them but note that they are well-regarded by a range of practitioners:

- *The Dark Side of Dharma: Meditation, Madness and Other Maladies on the Contemplative Path* by Anna Lutkajtis [189]
- *Breaking Open: Finding a Way Through Spiritual Emergency* by Jules Evans and Tim Read [99]
- Jack Kornfield's *A Path With Heart* is a Buddhist Modern guide suitable for beginners [164]
- *Seeing that Frees* by Rob Burbea is a resource for those with a basic understanding of mindfulness [47]
- Daniel Ingram's *Mastering the Core Teachings of the Buddha* is a detailed secular-ish technical manual [150]
- *The Manual of Insight* by Mahāsi Sayādaw is a comprehensive traditional Theravada Buddhist text for experienced practitioners [264]

Non-Buddhist-inspired works are less common and you may have to do some searching or find a teacher. There is the Christian movement of Centering Prayer, Sufi Khalwa and Maqam, meditative traditions in Kabbalah, and Yoga and Advaita Vedanta under the Hinduism umbrella. Additionally, although we do not know how well it fosters unitive and non-dual insight, the Acceptance and Commitment Therapy model is a system for fostering mindful and values-based action [134]. As such, it may provide a helpful secular framework for exploring some of these concepts, depending on the goals for such exploration.

4.3 **Assessing Whether the Session Worked

It's not always clear to people whether a session was helpful. We have a few suggestions:

- We think [therapy hangover](#) is such a reliable indicator of [reconsolidation](#) that you can use its presence or absence to determine whether you successfully reconsolidated some maladaptive [schemas](#) during the session.
- We've observed that successful reconsolidation often follows a pattern of emotional engagement with the maladaptive schema followed by dissipation of that emotion or loss of interest in that subject.
- Ecker et al. [85] describe the following signs of a completely reconsolidated schema:

A specific emotional reaction abruptly can no longer be reactivated by cues and triggers that formerly did so or by other stressful situations.

Symptoms of behavior, emotion, somatics, or thought that were expressions of that emotional reaction also disappear permanently.

Non-recurrence of the emotional reaction and symptoms continues effortlessly and without counteractive or preventive measures of any kind."

4.4 Making Sense of the Experience

**When applying scientific studies to one's own life and health, it is important to remember that the data we glean from these studies flattens a wide variety of individual responses by combining them into readable averages. You as an individual may experience something very different from the average participant of any given study, and that may be totally normal and fine. Some examples include: you may be much more or less sensitive to the psychological or physical impacts of MDMA, the medicine may impact you for a greater or lesser amount of time than it impacts the average person, you may experience more healing, faster, than the average study participant, or you may not be helped by MDMA at all. Many normal human variations, like low or high body weight, recent pregnancy, or menstrual cycle status clearly have an impact on many mental health interventions (especially when it comes to effective dosage), but are not typically studied. One of the great frustrations of mental healthcare research is that every real life situation is infinitely complex, and a corresponding infinity of confounding factors have the potential to influence outcomes. We encourage you to discuss with your clinician any difference in what you are experiencing (during any mental health intervention) from what the average response is that you might have expected from the research. It's important to both keep an eye on any health and safety concerns that might be related to your response, while also remembering that the range of normal and healthy responses to any mental health intervention is much broader than the averages suggest.

The intense emotions and beliefs you felt during the session may have been the [schemas](#) that have been negatively affecting your life. You will react and think differently now after the emotions and beliefs of your schema have updated. Pay attention to what thoughts and reactions are different from before the session, and you will learn how the [trauma](#) shaped your feelings and behaviors in the past. Common ways to identify these differences includes journaling, nature walks, making art, body movement practices, listening to recordings of your sessions if you self-narrate during the session, meditation, and talking through your experiences with an emotionally skilled friend or clinician [214].

When a schema is healed you should notice that although the pain and maladaptive beliefs and behavior are diminished, a level of caution remains. If this caution is helpful rather than overwhelming, then this is the schema in its adaptive, rather than maladaptive form. This caution will aid you in avoiding future harm.

You might have had profound feelings or thoughts about various belief systems, socio-cultural systems, organizations, etc. MDMA can spur profound insights. The feelings of trust, safety, and increased perspective inherent to many MDMA experiences can cause us to take the profound thoughts and feelings we have during those experiences as objective truth, which they may or may not be [136]. [Psychedelics](#) inflate feelings of meaning. Rather, MDMA can offer a new perspective based on a state of heightened, but incomplete compassion and safety. Even in this exceptional state, all your still-unconscious emotions are deeply influencing your beliefs and feelings. Your more reliable tools of discernment, compassion and cognitive and emotional flexibility, will gradually improve as you continue [reconsolidating](#) schemas. Using that increasing flexibility and compassion to rigorously and critically engage with a diverse and challenging set of reliable information and experiences will more reliably lead you to what is objectively accurate or helpful for your life than profound session insights [30]. Seek high quality critiques of your beliefs and incorporate beliefs into rigorous

higher level frameworks [260]. Correct for cognitive biases and aim for a balanced perspective when evaluating new ideas [114].

PTSD makes us feel as though we are by our nature isolated; MDMA can help people feel as though they are by their nature connected to one another. This may be one of the central mechanisms of healing that both therapy and MDMA provide.

As Cashwell et al. [51] state, spiritual bypass "...occurs when a person attempts to heal psychological wounds at the spiritual level only and avoids the important (albeit often difficult and painful) work at the other levels, including the cognitive, physical, emotional, and interpersonal." This results in maladaptive patterns and interrupted psychological development. The term was introduced by John Welwood, a Buddhist teacher and psychotherapist. Because MDMA can produce profound spiritual experiences for those individuals who interpret their MDMA experience in a spiritual way, it may be important to take care to avoid spiritual bypass if MDMA experiences are to actually facilitate healing. In particular, the profundity of many MDMA experiences may lead one to feel that focusing on painful maladaptive schemas is simply no longer necessary; however, without that focus, the schemas will not be reconsolidated, and healing will not be accomplished to the degree it otherwise could be.

Sometimes individuals may feel they are receiving a message from the medicine, stating that their healing is complete and further medicine work is not appropriate or useful for them [244]. Alternately, the message may take a form like, "the medicine has done all it can do for me, and now I need to focus on some specific practical aspect of my life." Although practical life circumstances can have an enormous impact on mental health, and we wouldn't want to discourage anyone from fighting for a healthier life situation, we caution individuals and clinicians who encounter this scenario to be mindful of the possibility that these messages may also be just be [avoidance](#). To understand what is insight and what is avoidance, it may be helpful to examine what symptoms and side effects remain active in an individual's life. It may also be helpful to spend time with the negative feelings about further medicine work in the context of reconsolidation exercises, whether assisted by medicine or otherwise. For further discussion of how to decide when to stop using medicine, see Section 4.5.

Healing experiences are often, to one degree or another, stressful. Although stress is often regarded as harmful in modern US culture, it is crucial to both meaning and personal growth. You only experience stress when things matter to you, and a stress-free life is a life of apathy and meaninglessness. It is stressful, but also helpful and important, to sit with the discomfort of a maladaptive schema or a [mismatch](#). Even our original traumas could not have harmed us if we did not value the things we value—trauma is intrinsically connected to meaning. As you progress, try to differentiate between adaptive stress, which may alert you to immediate dangers or motivate beneficial actions, and maladaptive stress—which is more than you are able to process or respond to in a healthy way. A good clinician or guide can help you gain insight into which stress is helpful for you and which stress is more likely to harm. A good clinician or guide who is up-to-date on the research on this topic can also help you re-frame stress in a way that greatly reduces its negative impacts on you, even on a physiological level. For a comprehensive discussion of the dual nature of stress and the importance of adaptive framings of stress, refer to *The Upside of Stress* [200].

****You may also have remembered events you weren't previously aware you experienced.**
The subject is too complicated and controversial to succinctly summarize here. We rec-

commend The Psychedelics and Recovered Memories Project [301] for a nuanced guide on psychedelics and recovered memories.

****Relatedly**, you may recall feelings or beliefs not clearly related to a specific event. These could come from early childhood, when emotional memories form before you are able to retain long-term episodic memories [43].

In Western culture we place a premium on having a continuous and linear narrative understanding of ourselves and our place in the world. This value set can serve to further disempower survivors of trauma, especially childhood abuse, because the nature of memory and the shame and taboo surrounding abuse experiences often preclude clear and objective understandings of what exactly happened in our childhoods. Additionally, the US (and possibly other places around the world) embodies a schism in cultural values regarding what is abusive and how abuse should be dealt with. In cases where abuse is extensively documented, survivors nonetheless may face aggressive gaslighting and extended abuse in response to speaking up about their initial experiences. Even documentary certainty about the actual events that happened is not always enough to endow survivors with the “good victim” status they are often seeking when they focus on the accuracy or inaccuracy of recovered memories.

In the face of these realities, you have to think: given that I can never know for sure what actually happened to me, then what? And what, as it turns out, is that you still deserve compassion and healing. “What” is also: that it can be reassuring to gather as much objective evidence as you can about your own history. This can be a way of reclaiming what you can of your own broken narrative, of knowing what is possible to know and at least laying hold of it. And you may need to grieve a great deal, because often the evidence is very thin, and a knowledge of your own history is one of the things that was stolen from you. But your deservingness of healing does not depend on someone coming along and saying, “I have a video of you suffering a legitimate kind of suffering, so your pain is valid now.” It may be helpful to explore the following questions, either by journaling on your own or by talking them through with a trusted/emotionally skilled friend and/or a clinician: what does it mean to me if X actually happened? What does it mean if Y happened instead, or Z? What does that say about my identity, my needs, how I perceive myself, and how others perceive me? What does it say about my future? What does it say about what I deserve?

Please be compassionate with yourself, as much as you possibly can. Whether your suffering is real and matters is a different question from, “what is the best strategy for addressing my suffering.” One last word is, your pain is trustworthy, even if your memories are not. If you feel like you are suffering, that is real, and it matters.

4.5 Continued Reconsolidation

****Gains** in functionality and emotional health often depend on [reconsolidation](#) of the underlying maladaptive [schemas](#) [85]. We guesstimate that accessing the maximum possible benefits from reconsolidation may take anywhere from single digit hours of [mismatching](#) for simple problems to thousands of hours for the most severe mental illness. These estimates do not include the overhead of uncovering schemas, finding mismatches, finding techniques that work for you, or developing relationships with a therapist. Because there are risks

from extremely high cumulative MDMA use [292], and because MDMA sessions have significant logistical or financial costs, we recommend using between-session non-medicine-assisted reconsolidation to maximize therapeutic progress.

******We have experienced that between-session reconsolidation exercises are often easier for some period of time following an MDMA session, possibly because it temporarily disrupts some self-reinforcing cycle of maladaptive schemas. If this occurs for you, and if you want to accelerate healing, we recommend spending more effort on and experimenting with reconsolidation exercises. You may even find that maxing-out your reconsolidation capacity every day will deliver very large amounts of therapeutic progress. Developing the skill of sober reconsolidation can reduce your therapeutic reliance on MDMA and allow reconsolidation in a wide variety of circumstances where MDMA use is not appropriate. When well-developed it also allows faster healing because the safety and logistical considerations of MDMA-therapy are no longer limiting.

******We have observed that significant amounts of reconsolidation often seem to happen without deliberate effort in the weeks and months following a session. We speculate that this phenomena may occur when the session [destabilizes](#) an attractor state enough to allow natural, gradual shifts of schemas over time [137].

******Based on MG's experience, we speculate that there is a daily mismatch limit (one date point suggests about 2 hours). At that point, [reconsolidation exhaustion](#) inhibits the practice. Sleep (or possibly just a sufficient length of time) seems to rejuvenate the ability. Reconsolidating to your limit every day will likely maximize your progress if you have the time and energy.

In addition to the explicit process of maladaptive schema investigation detail in Section 4.11, we think any [defense cascade](#) activation (see Section 2.1 for symptoms) or non-useful fear, anger, anxiety, etc. in daily life outside of immediately dangerous situations is a valuable indicator of maladaptive schemas. Furthermore, we pervasively practice subtle, barely-noticeable [avoidance](#) around a wide swath of uncomfortable ideas, places, people, etc. We think noticing and going toward the object of avoidance is usually a fruitful endeavor.

Structured Reconsolidation:

Ecker et al. [85] breaks the psychotherapy reconsolidation process into 7 steps, which we quote here:

Preparation (Accessing sequence)

- A. Identify symptom
- B. Retrieve target learning (symptom-generating schema)
- C. Identify contradictory knowledge

Transformation (Unlearning sequence)

- 1. Reactivate target learning (B)
- 2. Co-activate contradictory knowledge (C)

3. Repeat pairing of (B)+(C)

Verification

V. Observe markers of target learning nullification:

- Emotional non-reactivation
- Symptom cessation
- Effortless permanence

Here we list various practices and medicines we think are particularly useful for additional healing between or instead of MDMA sessions. Those doing solo healing may find more or less luck attempting these methods on themselves. We suggest, if therapist cost or availability are significant barriers, that at least a few sessions with a trained professional can be greatly beneficial to learning a technique. Many therapists also offer video-therapy available from anywhere with a good internet connection. Therapists are often legally prohibited from working with clients outside their state or country of licensure, though this is usually only a problem if you tell them where you are located.

- **Unwinding Anxiety App:**

- **Coherence Therapy:** This method is one of the few explicitly grounded on the principals of memory reconsolidation [85]. We recommend the thorough summary and assessment by Sotala [285] for an introduction to the framework. Interested readers can follow up with the book by Ecker et al. [85]. A directory of trained therapists is maintained by Coherence Psychology Institute [62].

- **Ideal Parent Figure Method:**

- One trial found that the Therabot AI therapist improves mental health [138]. Note that one PubPeer comment claims methodological errors in the study significantly lower the effect size [16].
- Thought Records (See Harper [132] for a worksheet.)

"Internalized MDMA-Therapy":

We suggest that powerful experiences of profound safety along the lines of "I will be whole and ok deep down no matter what happens", from MDMA, mystical, spiritual, or meditation experiences, are of exceptional therapeutic benefit between sessions. When you notice avoidance, anxiety, reactivity, distress, or other signs of maladaptive schemas in daily life, recalling and staying present with your feeling of profound safety can mismatch and reconsolidate your maladaptive schema in the moment. We have heard multiple anecdotes that practicing this technique makes it easier and more automatic. In two cases, hundreds of hours of practice led to mismatch and reconsolidation happening without conscious intent any time a maladaptive schema is activated and the individual is not actively avoiding it. This ability may reduce or eliminate the need for MDMA-sessions when well-developed.

We think developing this ability is valuable for a few reasons: it enables a higher volume of reconsolidation, helping you reach therapeutic goals sooner; long-term MDMA use could have side effects; MDMA-sessions require planning and recovery; and reconsolidation is valuable in many contexts where MDMA use is not appropriate.

This method seems to use a different series of steps from the reconsolidation steps outlined above:

1. Identify current distress (fear, anger, etc.)
2. Co-activate universal contradictory knowledge (possibly [non-dual](#) awareness)
3. Repeat pairing
4. Observe markers of target learning nullification (You don't need to continue this step once you're sure the method works.)

MG reports that with practice this process can become automatic and occur without deliberate intent, or even occur in the background while doing other activities.

We also propose that powerful experiences of total safety during a session can later act as a compass you can compare all other experiences to, to deduce if a certain feeling is maladaptive or not. As with real compasses it only measures the direction in which to travel; it can't tell you how far away the destination (reaching particular therapeutic goals) is.

If you haven't had a powerful experience of profound, universal safety, context-specific mismatches will have to be found for each maladaptive schema. It may take some effort to find contradictory knowledge or memories of contradictory experiences, but when found, that memory can also be recalled for in-the-moment reconsolidation of specific schemas. We also suspect, based on one case report, that highly-skilled compassion meditation can be directed toward distressing schemas to contradict them.

We speculate that this type of reconsolidation is similar enough to high-level insight meditation that extensive use can produce many of the same effects to your sense of self. See [4.2](#) for resources on managing this process. If this process does destabilize your sense of self, it may also luckily provide the solution. MG reports that existential distress on this topic can be reconsolidated using the same process that produced it.

4.6 Making Positive Life Changes

Some people may find that as they [reconsolidate schemas](#) and have positive disconfirming experiences, they have less need for compulsive self-soothing over time. They benefit from the therapy not just through reconsolidation, but through the support that the subsequent peace and perspective provide for positive behavioral changes. Sometimes being in a rut is the function of inertia; sometimes it is self protective, and improved regulation or a sense of new experience or perspective can help a person break out of it.

How MDMA Impacts Behavioral Change Goal Selection

We advise refraining from drastic life-shaping decisions immediately post-session. MDMA insights may sharply highlight certain aspects of a situation which you had not been facing or focusing on before the therapy. Although these insights may be extremely important, we feel they can best be understood in the broader context of your life both before and after the MDMA session and the immediate post-session period.

We recommend avoiding major life changes during the immediate post-session period unless (1) you have wanted to make those changes for a significant time prior to your MDMA experience, (2) you are (and have been) very sure and very committed about the change you want to make, and (3) you have access to other forms of support around that change, for instance, regular social connection with individuals who enact the behavior you are interested in adopting, an accountability buddy, etc. (See below for further discussion of structural supports.) When these three conditions are met, we are hopeful that MDMA neuroplasticity could provide a helpful layer of support for larger behavioral and lifestyle shifts.

On the other hand, MDMA therapy may more routinely facilitate a “baby steps” approach where individuals make small changes as they feel capable of making them, with the neuroplasticity window providing an opportune time to build positive habits and process emotional memories.

Barriers to Behavioral Change + Resources to Support Selected Changes

Most people have some habitual behaviors they have wished to change for a long time. In this section, we will review common reasons people struggle to make behavior changes they want, and offer an overview of strategies for overcoming these barriers. Additionally, we have included a fairly comprehensive appendix (see [E](#)) of evidence based recommendations for behavior changes that are likely to have a positive effect for most people who implement them. It includes at least one recommended resource about each of those changes. We hope this appendix will assist readers in identifying the behavioral changes with the lowest cost and the highest reward possible, including changes they may not have previously considered as possibilities. Additionally, we hope the information throughout this section will support our readers in using their neuroplasticity windows as effectively as possible, and that behavioral change efforts in the aftermath of therapeutic MDMA use can amplify the benefits of these interventions.

Many people feel puzzled or frustrated by their inability to enact important behavioral changes that they know would improve their quality of life (like following through on daily exercises prescribed by a physical therapist), or which are strongly aligned with their values (like ceasing porn use to adhere to religious values, or adopting a vegan diet to reduce carbon footprint). In modern US culture, individuals often judge and blame themselves for “not having enough willpower” to successfully make these changes. For some, this can be a perpetual source of shame: because of their failure to enact desired behavioral changes, they begin to attribute negative characteristics to their identity, to consider themselves to be apathetic, stupid, lazy, a bad friend/partner/parent/student/employee, or whatever other

negative identity might apply to the situation.

However, research shows that the individuals who are most successful at making these kinds of changes are also (1) likely to frame their shortcomings in terms of behavior (creating guilt) rather than framing them in terms of identity (creating shame), and (2) likely to engage a greater level of structural support for their desired behavior change. Finally, most behavioral health goals have a strong emotional regulation component, even beyond the intensity of a shame response.

Structural support can broadly be categorized as “trigger supports” and “access supports.” Trigger supports relate to what initiates a particular behavior. “Tiny Habits” gives the example of a woman who wanted to get up early and exercise before work, but found herself using the time after her alarm went off in the morning scrolling through her phone instead. After considering several possibilities, she started using an alarm clock and leaving her phone in the kitchen overnight. This removed the trigger for the behavior she was trying to avoid. Other examples of trigger support would include a parent reminding their child to do chores, or someone who wants to spend some time reading every day leaving their book on the couch cushion where they typically sit upon coming home from work. Access supports are things that reduce the level of effort it takes to engage in a desired behavior. A home washer and dryer unit would be an access support for someone with the goal of keeping up with their laundry needs; a private chef, or a week of “meal prep” in the fridge, would be an access support for someone who is trying to adjust their eating habits. A “dumb phone” and a social working environment with co-workers who feel safe and are supportive of the goal would be access supports for someone whose goal is not to scroll through the internet while they are at work. Creative and extensive use of structural supports can make all the difference in behavioral change success.

Finally, the emotional regulation component of behavioral change is frequently underrated. People often attribute their inability to enact a desired change to motivation or willpower problems, and then beat themselves up for these perceived failures. The more constructive approach is to implement applicable trigger supports and access supports, and then, if motivation still seems to be a problem, to engage with motivation enhancing strategies such as setting up a “fishbowl,” or using the other social accountability strategies detailed in Appendix

Procrastination is most centrally an emotional regulation problem; it emerges from feelings of overwhelm, often followed by shame about the procrastination itself. The single most effective strategy to address procrastination, in my clinical experience, is to practice breaking tasks down into manageable parts. If the procrastinated task is getting out of bed and taking a shower while severely depressed, this might look like calling a friend, then talking through and enacting the process of throwing the covers back, putting one foot on the floor, putting the other foot on the floor, walking towards the bathroom, opening the door, and so on. If the task is an hour long marketing presentation, the first step in ending procrastination might be talking through with a mentor how to break the project down into the smallest parts possible.

Self-destructive behaviors generally are associated with feelings of shame. We recommend the work of Brené Brown Ph.D. on shame resilience [41].

Behavioral Change Goal Selection in the Age of Addiction

In the words of Anna Lembke: “We’ve transformed the world from a place of scarcity into a place of overwhelming abundance: drugs, food, news, gambling, shopping, gaming, texting, sexting, Facebooking, Instagramming, YouTubing, tweeting... the increased numbers, variety, and potency of highly rewarding stimuli today is staggering. The smartphone is the modern-day hypodermic needle, delivering digital dopamine 24/7 for a wired generation. If you haven’t met your drug of choice yet, it’s coming soon to a website near you. Scientists rely on dopamine as a kind of universal currency for measuring the addictive potential of any experience. The more dopamine in the brain’s reward pathway, the more addictive the experience.” -Dopamine nation, Chapter 1

Addiction is a complex and overwhelming phenomena, with biological, psychological, social, and structural components. It exists on a spectrum of compulsive behaviors. A person’s desire to change their relationship with a given substance or behavior can vary widely: on the one end, someone may want to stop eating fast food on twice-yearly road trips when they already never eat it at any other time. On the other end, someone may have a desperate need to retrieve their life from the encompassing grasp of methamphetamines or heroin. Although it has become socially acceptable to joke or vent about our less destructive addictive tendencies, (like a coffee addiction or a social media habit that isn’t ruining our employment and hygiene) our current societal, economic, and technological structures generally provide poor support for individuals struggling with addictive tendencies at all levels. Individuals use substances and behaviors that have negative consequences because those substances and behaviors solve some kind of problem for the individual who uses them. The most effective way to assist individuals who are struggling with these kinds of harmful coping patterns is typically multi-pronged. It might include any or all of the following:

- medication assistance (buprenorphine is highly effective and safe for opioid dependence [198]) to reduce cravings for a harmful substance
- opportunities to contribute to and connect with their communities in meaningful ways while sober
- peer support
- psychotherapy
- case management (helping the individual access a variety of needed contexts and resources)
- contingency management (creating accelerated and enhanced positive and negative consequences supporting the desired behavior changes)
- other executive function support, such as tailoring the living environment to support the preferred coping choices and building healthy habits like sleep and meditation, which support impulse control
- intensive medical and psychiatric management of any underlying issues that have induced them to use the harmful coping mechanisms.

The average individual who struggles with addictive behaviors, far from being able to bombard the problem from all sides as I’ve described above, is shamed for not being able to simply choose to stop using the harmful coping mechanism. This typically increases use of the harmful behavior or substance. In short, we live in an age where addiction has been aggressively stigmatized/shamed and resources for treating it denied, while resources and structural support for maintaining addiction have been amplified. “Crossover addiction,” where individuals who struggle with one addictive coping practice simply shift their dependence onto another addictive coping practice, is pervasive. Although we would all like to see ourselves as independent decision makers, we increasingly live in an attention economy where massive investment has been made in competing for each nanosecond of our attention.

It is increasingly difficult to capture those moments of our own attention back, and to focus them on our safety, flourishing, freedom, and connection with others.

To make matters worse, despite emerging from the “overwhelming abundance” Anna Lembke describes above, addiction creates scarcity. It creates a scarcity mindset regarding access to the coping mechanism, whether that’s time for gaming or money for heroin, and in its worse iterations, it inspires compulsive behaviors that are financially, socially, and medically destructive in the extreme. Just as important for the problem of escaping addiction, it perpetuates scarcity around meaning and human connection. Addictively patterned coping mechanisms numb feelings all around, impeding our ability to be vulnerable and connect deeply with one another and with the things we find important in life. In rats, non-heroin-using individuals were found to help a fellow rat escape from a trap, while heroin using rats didn’t bother.

Second, despite the dystopian background, strategic habit development can (with commitment over time) provide access to cornerstone strategies on which to build a better life. To select a behavioral change goal that’s right for you, consider your own motivation, your life experience, the degree to which the behavior change offers benefits across a range of life domains. For instance, regular exercise or meditation can help many individuals with pain management, depressive symptoms, and physical health. To find the right foundational habits for you, you’ll need to consider your individual supports, accessibility challenges, and barriers. We make some general suggestions that are beneficial for a majority of people in [Appendix E](#).

A harm reduction framework is both evidence-based and essential when addressing addictive coping patterns. I once read (maybe in the book “tiny habits?”) that the most important characteristic for personal growth is the ability to experience satisfaction from small victories. Abstinence is an excellent goal for many people in many situations, but if you are not interested in abstinence or if abstinence is not realistic for you right now (or if your addictive pattern is around food or screen time, which are not realistic to totally abandon), your welfare may depend on your ability to give care to yourself by identifying the harms your coping mechanism creates, and mitigating those harms in more realistic ways. There are incremental victories to be had that make a significant difference in the level of harm an addictive coping mechanism creates in a person’s life. You may reduce the amount you use, or regulate the timing (only after work), or refrain from mixing multiple substances or from gambling in the first three days after your paycheck comes in. If you are not ready to stop drinking, you may focus on making sure that you get all your driving and work accomplished before you start drinking each day, and that you stay hydrated and eat some healthy food on the regular. Maybe you want to start meditating for three minutes each day before you start drinking. These measures are meaningful. They reduce harm, improve your quality of life, and will leave you in better shape if the day comes when you are ready to make bigger changes. It’s important to adopt a mental framework (and cultivate a support system) that sees the value of small improvements and supports you in making the changes you are interested in and ready to make.

4.7 **Afterglow

Some people experience a temporary afterglow (wellbeing, mindfulness, less mental illness) for days-weeks after some [psychedelic-therapy](#) sessions [101]. We have seen a variety of anecdotes that MDMA sometimes also induces afterglow. We caution against chasing after it with more frequent MDMA doses. Afterglow is often unreliable, while [reconsolidation](#) provides durable, long-term healing that does not require continued medication. Carhart-Harris and Friston [48] speculates that afterglow is an enduring relaxation of all [schemas](#).

4.8 **Long-Term Trends of Therapy

In our somewhat educated guess, accessing the maximum possible benefits from [reconsolidation](#) may take anywhere from single digit hours of [mismatching](#) for simple problems to thousands of hours for the most severe mental illness. Because of this, those with severe mental illness may only perceive relatively small week-to-week gains in symptom improvement even at the maximum daily mismatch limit. These small gains can add up to more visible improvement on a monthly timescale. Long-term progress also often feels non-linear. Therapeutic [destabilization](#) may make things feel worse at times, or extended periods of reconsolidation may only yield visible results at unforeseen turning points.

4.9 Managing Adverse Symptoms Outside the Session

**There are multiple practical objectives in healing. Keeping these balanced determines the pace and methods of healing:

- Healing as soon as possible to minimize suffering and improve function.
- Healing that is durable rather than fragile.
- Developing skills to process future maladaptive [schemas](#).
- Avoiding major disruptions to your life from therapeutic [destabilization](#) or other adverse medical and psychological effects.
- Minimizing cost.

Therapeutic destabilization may intensify as [dissociation](#) diminishes during therapy, surfacing previously unconscious memories and potentially causing heightened distress [311]. While destabilization, to some extent, is an inherent aspect of [trauma](#) therapy, the intense nature of [psychedelics](#) can evoke particularly intense responses. This is especially so for those with complex trauma, though self-awareness of such trauma can be elusive due to [avoidance](#) and dissociation. Different anxieties may surface and calm at different points throughout your healing journey.

**Robinson, Evans, Luke, et al. [249] surveyed people who have experienced prolonged post-psychedelic difficulties about what coping strategies helped them. This study did not focus only on MDMA or therapeutic use, so these results may only partially apply here. The

most common techniques people found helpful, in decreasing order of commonality were: peers and community support, meditation and prayer, professional therapeutic or coaching assistance, self-educational reading about the issue, physical exercise, breathing techniques, journaling, acceptance and surrender, embodied contemplative practices, and time in nature. When receiving emotional support, participants most commonly reported the following as helpful: talking and feeling heard, acceptance and validation, and shared similar experiences. The linked document has the full lists.

Anxiety, Panic, and Dissociation:

- **Distraction**

- Mindfulness: Using mindfulness practices (as detailed in (see Brach [37] and Smookler [283])) to connect with the present moment, one can observe and accept emotions without reacting as strongly.
- 5-4-3-2-1 Sensory Awareness: Noticing five things one can see, four one can touch, three one can hear, two one can smell, and one one can taste.
- Progressive Muscle Relaxation: Tensing and relaxing muscle groups to reduce physical tension.
- Intuitive eating
- Activities to calm yourself, such as warm baths, music, art, nature walks, pleasant scents, hot herbal tea, reading, interacting with pets, etc.

- **Safety**

- Weighted blankets, holding an object, or touch from a trusted person.
- Visualize a safe space where you feel like your truest self. Imagine vivid sensations (e.g. the feel of your bare feet on a forest floor, if that's comforting to you) to increase its power.
- Imagine a safe container or box where difficult memories can be stored until the next session.
- Safety mapping is a valuable tool for identifying sources of safety and threat in your life (See 3.7 for more information.). Once you have done this exercise you can use this information to: 1) Imagine a safe, comforting scenario when you feel overwhelmed. Imagine vivid sensations (e.g. the feel of your bare feet on a forest floor, if that's comforting to you) to increase its power. 2) Set boundaries around stimuli that activate challenging schemas. For example, you could tell someone you feel overwhelmed when they talk about a particular topic, and you would appreciate them avoiding it.

- **Psychoeducation** Knowledge of trauma and its effects can make your reactions more understandable and predictable. We suggest the materials in Appendix A.

- **Feeling and Symptom Tracking** /

- **Establish Predictable Routines** Regular routines in your daily life can provide a sense of normalcy and predictability.
- **Social Support** See Section 3.6.
- **Crisis Plan:** Make a plan for what to do if symptoms become overwhelming.
- **Reconsolidation** Reconsolidating the relevant schemas, possibly with more MDMA-therapy, will relieve anxiety, though not quickly if the anxiety is complex. See Section 4.5.
- **Unwinding Anxiety App**
- **Medication**
 - The prescription medication propranolol may stop some of the physical symptoms of arousal and fight-or-flight (though not the underlying schemas) by inhibiting adrenaline receptors [288]. The UK National Health Service recommends 40mg 1-3 times daily [220].
 - Kava reduces anxiety [233]. Side effects when used for less than 24 weeks are mild, infrequent, and transient. Longer term efficacy and safety is poorly studied.

**Sleep Problems

- *Cognitive Behavioral Therapy for Insomnia (CBT-I)* has high-quality evidence for effectiveness. Stanford Medicine has a guide that seems easy to follow yourself [287].
- Melatonin is generally safe (long-term use is poorly studied) and it's efficacy for sleep disorders without comorbid mental illness is well-established, but it is poorly studied for sleep problems caused by anxiety [216]. The UK National Health Service recommends a 2mg extended/slow release pill taken 1-2 hours before bed [219].
- There are a variety of prescription medications. Note that long term use of benzodiazepines is addictive, ineffective (because of tolerance), and causes long-term cognitive impairment that persists even after discontinuation [24].

These are options, not prescriptions. This list has been carefully ordered to prioritize what is likely to work best, based on statistical averages. I hope there are some things here that will work for you, but everyone is different, and if the nothing on this list works for you, that's something wrong with the list, not something wrong with you.

- **Choose distraction over denial:** It can delay your healing to deny that you're having feelings at all—which is tempting to do when the feelings are very overwhelming. However, it is also important to feel and process your feelings on your own timeline; when you are feeling more than you are ready to feel, distraction can be extremely nourishing and helpful. Can you focus on self-care tasks? Is this the moment to organize your art supplies or clean out your closet? Is there some form of work that feels accessible and/or good to you right now? Or maybe there's a movie or a video game or an Instagram or a comic that can provide a great distraction.

- Exercise is the single most efficient way to complete the stress cycle and release anxiety. Try vigorous exercises (like jumping jacks) for a short period of time. If that isn't your jam, slow, gentle options like trauma informed yoga [117], tai chi, or a walk outside can also be extremely effective.
- This deep muscle relaxation technique [309] is a great second choice with good data behind it.
- It might be possible to reduce your anxiety by stopping your physical anxiety response, which can then help your emotions mellow out. Physiological hacks that do this are called vagal maneuvers [77]. One of them is the “diving reflex,” which some people can activate by holding ice packs (or, in a pinch, a cold drink or two) to their face.
- If you have access, maybe spend time in nature—people consistently underestimate how much better time in green space makes us feel. Even five minutes can have a measurable positive impact.
- If you are not currently experiencing physical danger, paying attention to what your body is experiencing right now may help create calm. One option is to name (out loud or in your head) what you are experiencing through your senses: I am hearing _____, I am seeing _____, I am touching _____, I am smelling _____, I am tasting _____.
- Try meditation or deep breathing exercises (See Brach [37], Smookler [283], and Kabat-Zinn [156]). Meditation can be a way of centering on physicality—you can try a body scan meditation, or a sensory focus meditation, or a myriad of guided meditation options.
- Connect with your friends: Start a text thread or a phone tree among your group. Share memes. Ask friends to send memes that remind them of you. Ask someone if they can just sit with you on a phone or video call, or read you some favorite children's stories.
- Seek physical affection: Gottman recommends a daily mindful six-second kiss. Hugging someone you trust for a full 20 seconds is also good. Pets or self-massage can also help.
- Ask for help. Asking for help can be incredibly vulnerable. Also, asking for specific things can be very hard when you're in distress—and it can feel pointless when you feel very deeply as though nothing could possibly make you feel better. However, even small gestures of support can make things a little more bearable until your body-mind is able to start healing itself. On top of this, giving people who care about you and/or want to support you some kind of job to do can build closeness and help them feel less powerless. Consider asking for: food, water or tea, someone to sit with you, someone to watch a movie with you, someone to text you on the hour and remind you that you are a badass.
- Sleep it off: if you're able to *get* to sleep, the schema will very likely be de-escalated when you wake up.

- If you are ready, or it feels like an OK idea, try writing about your experience. Writing has been shown incredibly effective at helping to address trauma—even fifteen minutes spent writing about trauma on one occasion has lasting positive impacts.
- Write about your experience using your non-dominant hand.
- Write or tell a friend or supportive stranger your “shitty first draft”—the story you’re telling yourself about who you are, what you’ve experienced, and what it all means.
- Alternately: make art. If you don’t want to make art about bad things you’ve experienced, try making art about something that has been comforting and nourishing to you in the past, or about what you wish you could escape to, or about what you are fighting for.
- Try a harm reduction approach when it comes to coping with substances:
 - Avoid using alone - if you are isolated, call a friend on the phone.
 - Avoid mixing substances or stacking doses
 - If you have been trying not to use substances or otherwise numb your feelings, and you end up doing numbing behaviors you had wanted to avoid, try to be very gentle with yourself. You always have a fundamental worth and dignity no matter what.

4.10 **Session Frequency

Although no research exists on the impact of varying time between MDMA sessions, we feel the following factors are worth considering:

- Sleep is likely important for in-session [reconsolidation](#) and post-session recovery [278]. People experience up to three days of post-session fatigue [179]. Starting another session before you have recovered from the fatigue of the previous one may reduce session effectiveness and increase the risk of undesirable effects. We know of two anecdotes of back-to-back [psychedelic](#) therapy sessions with no recovery days triggering psychotic episodes.
- Tolerance to MDMA starts developing within 1-2 hours of ingestion [102, 229]. We have been unable to find any data showing how long this tolerance lasts and distinguishing the effects of tolerance from [dissociation](#), [avoidance](#), or the natural variation of sessions may be difficult. However, if you notice a pattern of diminishing effects, we suggest experimenting with spacing sessions further apart or reducing dose. Using higher and higher doses to overcome tolerance may be a sign of behavioral addiction.
- We have observed that people often report that between-session reconsolidation exercises are for a period after the session. If this occurs for you, and if you want to accelerate healing, we recommend spending more effort on and experimenting with reconsolidation exercises (See Section 4.5) in this period rather than more frequent

MDMA use. You may even find that maxing-out your reconsolidation capacity every day will deliver very large amounts of therapeutic progress. Developing the skill of sober reconsolidation can reduce your therapeutic reliance on MDMA and allow reconsolidation in a wide variety of circumstances where MDMA use is not appropriate. When well-developed it also allows faster healing because the safety and logistical considerations of MDMA-therapy are no longer limiting.

- We have observed that some sessions may be either psychologically stabilizing or [destabilizing](#) depending on what [schemas](#) are activated in your life. If you find your sessions consistently destabilizing to a degree that is causing you major problems, waiting longer between sessions may reduce the effects of destabilization. In this circumstance we also recommend a combination of professional support and proactive self-care strategies like the ones listed in Section [4.9](#). Traditional psychotherapy may be less destabilizing than MDMA-therapy.
- One of the most important aspects of psychological counseling is a therapeutic alliance, which can be understood as “The bond between client and therapist; the collaborative approach and agreement on treatment goals; the collaborative approach and agreement on treatment tasks”, as described by Greenspace [\[126\]](#). The quality of therapeutic alliance is a major predictor of the effectiveness of psychotherapy. We suggest that for individuals who are unable to establish a therapeutic alliance with a conventional mental health practitioner, or who are unable to access a mental health practitioner with whom they are able to establish/maintain a therapeutic alliance, MDMA can offer a first foothold in the healing of [trauma](#). The medicine can be particularly helpful if transference (attributing feelings actually about other people and circumstances to the clinician or therapeutic process) becomes an obstacle to healing. In some cases, it does this by allowing the client to feel some degree of [secure attachment](#) to the MDMA as a parent figure. Sometimes, this can then be developed into a needed on-ramp to access other healing modalities. Thus, one of our concerns about keeping a low frequency MDMA interventions is that this opportunity could be missed, or time could be wasted. A critical mass of support for a briefer period of time can allow someone to become more self-sufficient or able to access community supports, whereas the same amount of support spread out over a greater period of time effectively perpetuates disability.
- As detailed in the safety section, an extremely high number of cumulative doses of psychedelics can cause valvular heart disease. It’s conceivable that chronic use also causes other, poorly understood problems, particularly for groups of people with certain genetic variants or health conditions.

MDMA eventually loses its effects for some people [\[102, 229\]](#). The reasons, prevalence, and applicability to therapy (rather than recreation) are unclear, though it has been associated with higher or more frequent doses. If you feel that you are reliant on MDMA for therapeutic progress, we suggest stopping recreational use in order to maintain efficacy for future therapeutic need.

We suggest Figure [4.1](#) as a high-level guide to the therapeutic process.

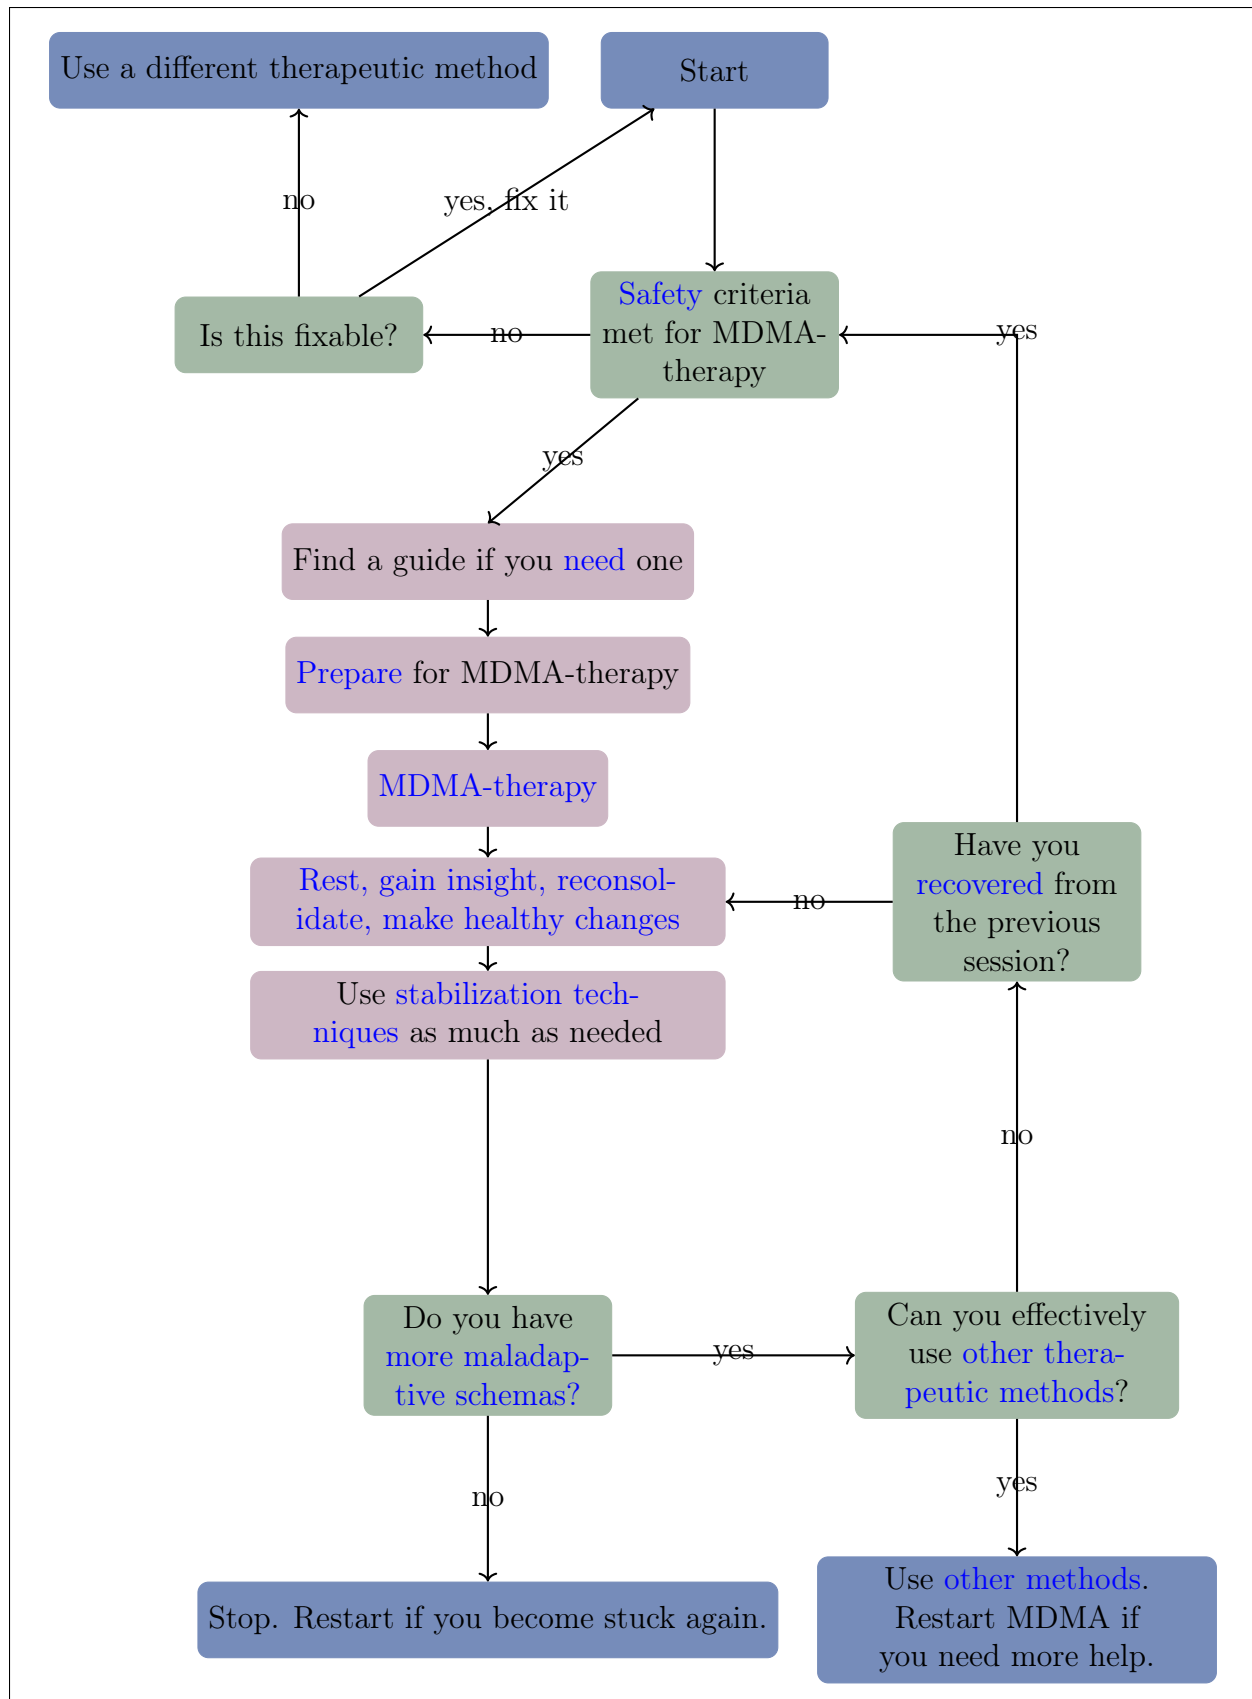

Figure 4.1: Generalized long-term therapeutic process.

4.11 ****Prompts for Uncovering Maladaptive Schemas**

Healing benefits increase as you continue [reconsolidating](#) maladaptive [schemas](#) [85]. In an ideal world, everyone would have access to as much strong clinical support as they need before, during, and after all of their reconsolidation efforts to facilitate the surfacing of maladaptive schemas. In the absence of that support, we use our experience to offer the following prompts to help you access the schemas that you may not be aware of, but which could be having a significant negative impact on your life. While there are no clear lines between the categories of prompts we offer, many of them directly relate to mental illness, while others focus more on assisting you with living the life of compassion, self-knowledge, connection, and flexibility that you may desire. Assisting you in finding pain points you have been unconsciously hiding from yourself is one of the jobs a therapist would have, but it is possible to do some of it on your own with tools like these. These methods attempt to elicit strong negative emotions, which are valuable signals that adequate emotional processing has not occurred. As discussed in the safety section, if you struggle with severe mental illness (including but not limited to suicidal ideation, mania, or psychosis) we strongly urge you to engage these kinds of prompts with caution and professional support.

We have experienced this kind of work to be positively transformative, satisfying, and deeply meaningful even for individuals who come into it feeling mentally well. As such, we recommend these prompts to anyone who feels at all interested in deeper self-knowledge, meaning, and connection with others. Many of these prompts are also useful for activating social biases which can be reconsolidated like most other maladaptive schemas. Additionally, we think a general principle of noticing and going toward objects of distress is usually a fruitful endeavor as long as you are physically safe. Similarly, we think most [defense cascade](#) activation (see [2.1](#) for symptoms) or fear, anger, anxiety, etc. in daily life outside of immediately dangerous situations is a valuable indicator of maladaptive schemas.

Love and Belonging

- Reflect on the pillars of early [secure attachment](#) (Appendix [C](#)) and the principles of Self Determination Theory (Appendix [D](#)). Think about how they were present or absent in your upbringing or current life. How do you feel about that? If this seems confusing to you or you draw a blank we suggest two things: Take an attachment assessment quiz [[296](#)]. Try the Ideal Parent Figure method (see Section [4.5](#)).
- Compassion meditation (See Kabat-Zinn [[156](#)]) can be distressing for individuals who are experiencing isolation, mistrust, or relational dysfunction. As such, it can be a helpful tool for identifying schemas related to these concerns.
- What makes you feel loved? What comes up for you when you do not feel loved?
- Do you feel like a certain group of people-perhaps sharing certain religions or political beliefs, or sharing a certain set of experiences or cultural practices-are “your people?” If so: what does it feel like, and what are your assumptions, when you are interacting with individuals outside that group? Do you feel 100% safe with individuals who *are* part of your group? Do you ever have experiences or desires that make you feel like

you are not as safe or accepted within your group? When do you feel like you “fit in” with your group, and when do you feel like you truly belong with them?

- What thoughts and experiences make you feel like you don’t have a place to belong?
- What stops you from feeling compassion, or from wanting to feel compassion?
- Have you spent time in environments where others prioritized your needs equally to their own? If so, how did that experience feel? If not, how does it feel to know you’ve never experienced that?
- Have you ever had the experience of not being appropriately valued, respected, considered, and cared for by others around you? What feelings are associated with that?
- What would it feel like (or what has it felt like) to go from feeling that you were not valued, respected, considered, and cared for, to feeling that you were? What would it feel like to give this gift to another person or being in your world?
- What makes you feel you are special to the most important people in your life? What comes up for you when you do not feel that you are special to them?
- Does it ever feel like you will not be lovable/loved if you are angry?
- Do you feel that you are wanted and lovable?
- Does it feel like you have to be very ill to deserve to be taken care of, or like you deserve care even when you are basically well? Why did you give the answer you gave?

Competence, Competition, and Safety

- If you could wave a magic wand and be better than any one other person you know in any one endeavor, what would you choose and why? What if the possibilities were expanded to include everyone in the world, even if you don’t know them? What are the runners-up, things that interest you, but are not your topmost priority? What does it mean about you that you are not currently able to surpass them in that endeavor in the real world? How would you answer these questions if all of your practical needs (money, physical health, etc.) were fully met?
- If you could take something away from someone because it does not feel fair to you that they have it, what would you take away, and from who? How many times would you repeat this process, with how many people, and why? If you could experience the positive feelings you associate with taking things away from others, without taking anything away from anyone, what would that mean or be like for you?
- Is there anything someone else has that you associate with your own unmet need, or the unmet needs of people you love? For example, if you have loved ones who struggle with housing insecurity, do you think about that when you drive through neighborhoods with extremely large houses?

- If you completed the Cartesian Plane of Safety in Section 3.7, think about the unsafe and safe items on this chart. Why is each item placed where it is?
- Think of things you feel angry, fearful, or anxious about.
- What makes you feel special compared to other people in your community, people who you meet, or people in the world? What comes up for you when you do not feel special, or when you do not feel "good enough"?
- Are there some sources of information that make you feel unsafe? What are the stories you are telling yourself about that information and those sources? For instance: how do you feel about information you are given by individuals or institutions who have harmed, mislead, or excluded you in the past?
- What things make you feel powerless? When you feel powerless, what do you reach for?
- Do you feel like you have to be strong?
- Do you feel like you can handle anything? If so: what would it mean or feel like if something were to happen in your life that you couldn't handle? Why do you think you feel the need to exclude that possibility from your imagination?
- Do you feel like you must justify your existence by doing something?
- How do you feel about groups of people or beliefs that are becoming more numerous or prominent, perhaps at the expense of your group of people or one of your treasured beliefs?
- How do you feel about the inevitability of frailness and death?

Self-worth and Identity

- Class, status, and money: If this is an area you are interested in exploring, consider reading through Building a Nuanced Understanding of Social Class or Compiled sliding scale questions by Harper [131] . What has your experience been? What do you wish it had been? What feelings come up as you think your way through the many dimensions of class?
- What makes you feel like you are not enough, and you do not have enough?
- On a deep gut level, what characteristics do you feel are appropriately associated with men, and what characteristics do you feel are appropriately associated with women? How does it make you feel when people (including yourself) conform to those characterizations? How does it make you feel when they (or you) *don't* conform to them?
- Complete the prompt "I want to be perceived as" and the prompt "I don't want to be perceived as" three times each with respect to a variety of the most important areas where people feel shame. See the shame triggers exercise in the Appendix B.

- How do you feel about your own anger? About your own sadness? About your own pride? About your own limitations and needs?
- Do you feel it's not right for you to be angry? Why or why not?
- Grief: Have you experienced major losses in your life that you are still struggling to face—losses that cause you to feel disorientation and longing? (Delineation of grief taken from “Atlas of the Heart” by Brené Brown Ph.D.). Are some of these losses the kind of thing (like miscarriage, the loss of memories held by a loved one with Alzheimers, loss of ability, or loss of an imagined future) that receive little or no social recognition or support? If you are experiencing this: can you articulate what it is you long for?

Meaning, Interconnection, Interdependence, Emotional Flexibility, and Spirituality

- What outcomes or ideals do you feel are worth sacrificing for? What kinds of sacrifices? How do you or would you feel if you were called upon to make these sacrifices? If you were to receive absolute moral certainty that you should not sacrifice for these outcomes or ideals, without having your feelings about those outcomes or ideals change at all, what would it feel like, and how would you react?
- What stops you from dreaming and wanting big things?
- What stops you from feeling that it's worthwhile to engage in projects that express your values in your community?
- Do you ever feel overwhelmed when you think about enacting values that are important to you?
- How does it feel when you have to make trade-offs between multiple things that you value?
- Do you experience self-judgement around how much you do or do not live out your values?
- If you find the concept of non-attachment compelling or appealing, consider visualizing permanent disconnection from your deep-seated attachments to one or more of the following: life, health, partnership, meaning, belonging, existence, status, being a good person, certainty, material comfort, order, sensory pleasures, and relationships. What emotions arise if you consider your fundamental assumptions about life, meaning, and self might not actually be true? Reconsolidating maladaptive schemas around attachment typically leads to equanimity and gratitude, not loss of healthy protective behaviors or basic attachments.
- Do you ever feel like you are responsible for the whole world?

Conflict, Collaboration, and Trust

- Looking at photos of people you have conflict with is often productive.
- Who is not worth collaborating with, and why?
- Who is not worth engaging in active conflict with, and why?
- If you could convince every important person in your life of one belief, what would it be? What if you could convince every person in your city, or every person in your country? How does it feel when others disagree with you about that thing?
- What makes you feel you are not being listened to, when you have a right to be listened to? What makes you feel disrespected? What comes up for you when you are disrespected, shut down, or ignored?
- How would it or does it feel to collaborate with others who disagree with you about important things? Would it be comfortable to collaborate with people who had 90% of your positions in common? What about 50%?
- How do you feel when others around you express anger, sadness, pride, limitations, or needs?
- What makes you feel angry?

Automatic Behaviors and Body-mind Reactions

- Do you have any escapist or addictive (not necessarily involving substances) patterns, including any related to MDMA? Are you using these to avoid or cope with distressing feelings [6, 112]?
- If there is a behavior in your life which you have repeatedly attempted to stop engaging in, without success, are you able to regard those attempts compassionately?
- If there is a behavior you engage in that you feel is clearly self-destructive, are you able to regard this pattern with compassionate curiosity and a desire to cultivate change? If not, what are you feeling instead?
- If there is a behavior you engage in that other people close to you feel is self-destructive, but which you experience as a strong positive in your life, what are your feelings about that conflict?
- Carefully expand your therapeutic environment to include stimuli that activate challenging schemas, as detailed in Section 3.7.
- How do you feel in your body after you spend two hours scrolling on your phone? Is it different for different activities?
- How do you feel about the things you own?

- How do you feel in your body when you think about your finances?
- How often do you feel fear or anxiety? What brings up these emotions for you? What do they feel like in your body?
- Stress or maladaptive schemas often cause physical symptoms in your body. Body-scan meditation (see Smookler [\[283\]](#)) is useful for locating these. Focusing on these physical feelings can activate and reconsolidate the associated schemas.

Chapter 5

Beyond Therapy

5.1 Expanding the Circle of Compassion

Cultivating empathy can enrich your connection to others and spur compassionate action, thus creating healthier societies and decreasing suffering. Research has identified three forms of empathy: affective empathy, cognitive empathy, and empathic concern. “Affective empathy” refers to having an emotional experience you believe you are sharing with another. Unfortunately, we are often inaccurate in our assessment of what emotions other beings are actually experiencing. “Cognitive empathy” refers to our ability to logically understand how others feel, and also why they feel the way they do-what all the contributing factors are, and how those factors work. Finally, “empathic concern” refers to our desire for others to have good things.

Among the helping professions, higher levels of affective empathy are associated with burnout and poor client care. When a caregiver is experiencing high levels of affective empathy, they are naturally motivated to address their own distress by helping the client with what they perceive is wrong-which may or may not have anything to do with what the client actually needs or is actually experiencing. In contrast, in these same populations, higher levels of cognitive empathy and empathic concern are protective against burnout and correlate to higher quality client care. As such, when we talk about cultivating empathy, we are talking about increasing your levels of cognitive empathy and empathic concern. To illustrate: suppose your friend is a father, who feels angry and powerless about his teenage daughter’s choice to dye her hair purple. You might feel affective empathy towards his powerlessness, relating to the way his status in the community might be negatively impacted by her choices. However, it may be that his distress is not connected to feelings about status, but only to concern about her welfare and what the change may signal about his daughter’s mental health. Your ability to effectively exercise compassion towards this father is contingent on the quality of your cognitive empathy-your ability to accurately assess and communicate where his needs, feelings and concerns are actually coming from.

Much of the existing research on increasing positive emotional states of kindness and compassion, associated with cognitive empathy and empathic concern, is focused on compassion meditation and loving kindness meditation. We feel that these practices are worth a try for most people (see Kabat-Zinn [156] for instructions), as they are correlated with

a number of positive outcomes. We also speculate that therapeutic MDMA sessions may offer an opportunity to jump-start or supercharge the process of cultivating cognitive empathy and empathic concern. Completing a compassion meditation during the MDMA session could be helpful for this. Alternatively, you might focus specifically on cultivating cognitive empathy through the following contemplative exercise:

During a session, look at photos of other beings and consider what you share with them, what facilitates their wellbeing, what they deserve, and what obligations you may have to them given the significance of their moral worth. As with a classical compassion meditation, you might start with yourself or someone who you find easy to generate compassion for, and then slowly by degrees work your way out through other categories of beings you may not feel as connected to. We believe non-human animals (and conceivably current or future artificial intelligences, though without any widely-accepted and experimentally validated theory of consciousness this is highly uncertain) are an important target for consideration and compassion because, as a large group of biologists and philosophers recently declared [15]:

First, there is strong scientific support for attributions of conscious experience [having subjective experiences; not necessarily being self-aware] to other mammals and to birds.

Second, the empirical evidence indicates at least a realistic possibility of conscious experience in all vertebrates (including reptiles, amphibians, and fishes) and many invertebrates (including, at minimum, cephalopod mollusks, decapod crustaceans, and insects)

Third, when there is a realistic possibility of conscious experience in an animal, it is irresponsible to ignore that possibility in decisions affecting that animal. We should consider welfare risks and use the evidence to inform our responses to these risks.

We posit that taking a holistic approach to compassion and cognitive empathy can avoid major oversights in our personal actions and beliefs, allowing us to maximize the benefits of a more connected and compassionate life by exercising compassion in areas where we otherwise might not have. Additionally, we posit that formalizing your compassionate impulses can sometimes lead to better prioritization and better outcomes. Both of these practices may assist us in expanding our moral intuition into new situations.

We also recommend that practitioners be cautious of major ethical readjustments during or after an MDMA trip, just as you would be with major life choice changes. Particularly high caution is warranted around actions that involve harm to some beings in the pursuit of a greater goal [19]. While we are sometimes faced with difficult choices, these types of actions often have toxic personal, organizational, and reputational effects. We recommend thinking through the many effects of your actions, including their larger systemic and relational impacts. Such actions are also commonly used as a, perhaps unconscious, rationalization of unconscious ego-related [schemas](#). We suggest that deeper exploration and [reconsolidation](#) of maladaptive schemas, including those listed in Section 4.11, will help you better align personal actions with the needs of all beings.

When recovering from [trauma](#), it is common for one's moral framework to become intertwined with maladaptive schemas-leading to unhealthy ethical frameworks like the "I must

save the world to be a valid person” belief Gabor Mate discusses in “The Body Says No.” (Also see Section 2.5 on [psychogenic](#) illnesses) At the same time, cultures and institutions often dismiss major harms-current examples relevant to mainstream US culture include childbirth trauma and the trauma of living through a mass extinction; past examples include enslavement or “resettlement schools.” In situations like these, we posit that traumatized survivors represent an important repository of experience, essential for crafting cultural shifts that could help avoid the future repetition of these and similar harms. As such, it is important not to dismiss the moral intuition generated by traumatic experience, but rather to approach it with compassionate curiosity, as one important source of insight among many.

5.2 ****Increasing Cognitive Flexibility**

We assert that cognitive flexibility is both highly important and lower than it should be for most people in the modern world. Intense tribalism seems to be a major reason why. It may have been selected for in a past where survival was much more tenuous than in it today for most people, and where societies were much smaller. While we still need to form coalitions (family, workplace relationships, friendships, etc.) to accomplish almost anything, we suspect our tribal tendency is overpowered for life in relatively safe nation-states. This creates all sorts of problems, such as poor governmental policy because of people voting based on identity [162] rather than good policy, being shunned for believing or doing things that have become a marker of belonging to a rival group, etc.

As the psychologist Pinsof [232] says on their blog about self-deception being a core aspect of tribalism:

We’re hyper-skeptical of claims made by the outgroup-the people we fear, dislike, and distrust. And we believe ingroup-flattering absurdities (e.g., “We were chosen by God,”) because it is instrumentally rational for us to do so. The benefits of status and tribal solidarity often outweigh the costs of false beliefs, particularly if those beliefs are vague, unactionable, or unfalsifiable.

We may also embrace harmful beliefs (e.g. bad political policy preferences) when most of the benefits accrue to us personally, but the costs are spread out among a large number of people. It’s like emitting pollution; it’s often the cheapest option for you, but the damage is spread over so many people that they have a very difficult time coordinating with each other to stop it [59].

It is common to perceive obviously false beliefs in the out-group. But how do you know they are wrong and you aren’t? The human capacity for self-deception must be strong enough to make at least one of you wrong about a supposedly obvious fact, but we have no foolproof a-priori reason to believe it is them instead of you. We think self-deception typically relies on [avoidance](#) of discomfort (being wrong, the potential for being shunned, knowing you have done something harmful, etc.). MDMA notably increases tolerability of discomfort and therefore we speculate it could be useful as an avoidance-decreasing tool useful for coming to more accurate beliefs about things people commonly deceive themselves about. For instance, during an MDMA session you might consider the implications of the hated political group being correct about some important piece of policy. This might bring

up fear of your social group shunning you for having this belief. We think MDMA might be able to [reconsolidate](#) this fear if that fear is maladaptive in some way. For instance, truth seeking may be maladaptive if you only have access to one social group, but in reality you may be able to switch to a different social group that is more tolerant of varying beliefs.

We live in a world of pervasive fear-based messaging and out-group demonization/dehumanization. Because of this, we believe additional strategies beyond reconsolidation are likely necessary to maintain cognitive flexibility and compassion in the long-run. We recommend two books on the subject that approach the topic from different angles:

- *The Scout Mindset* by Julia Galef [[114](#)]. "When it comes to what we believe, humans see what they want to see. In other words, we have what Julia Galef calls a "soldier" mindset. From tribalism and wishful thinking, to rationalizing in our personal lives and everything in between, we are driven to defend the ideas we most want to believe—and shoot down those we don't.

But if we want to get things right more often, argues Galef, we should train ourselves to have a 'scout' mindset. Unlike the soldier, a scout's goal isn't to defend one side over the other. It's to go out, survey the territory, and come back with as accurate a map as possible. Regardless of what they hope to be the case, above all, the scout wants to know what's actually true.

In *The Scout Mindset*, Galef shows that what makes scouts better at getting things right isn't that they're smarter or more knowledgeable than everyone else. It's a handful of emotional skills, habits, and ways of looking at the world—which anyone can learn."

- *Why We're Polarized* by Ezra Klein discusses the self-reinforcing feedback loops between our fears and identities and the behavior of the media and politicians [[162](#)]. This cycle increases polarization, political dysfunction, and separates us from each other. This book is more about understanding identity in politics than suggestions on how to improve the situation.

Glossary

Adverse Idealizing Transference (AIT) Idealizing Transference is a phenomena in which clients develop strong positive feelings towards their therapist [76, 144]. Sometimes this idealization can be intense enough that an unscrupulous or unskilled therapist may exploit (intentionally or not) the client for emotional, sexual, or financial gain, creating severe trauma for the client.

Alexithymia Consistent difficulty in noticing, identifying, and describing emotions [142]. This inhibits reconsolidation. The causes are not well-established.

Arousal The first step when a potential threat is noticed and assists in further assessing that threat [166]. It is also preparation for more intense defense responses like fight or flight, freeze, or immobility. Heart rate, breathing, and muscle tone increase, saliva is no longer produced, and core muscles tighten to stabilize posture.

Attachment Theory/Styles Attachment theory is a model which posits that emotionally secure attachments formed in the first 18 months of life serve as the foundation for emotional and psychological development throughout one's life [43].

Avoidance Physical or mental activity that directs attention away from distressing schemas and inhibits reconsolidation. Short term avoidance can be healthy if used to temporarily postpone dealing with a problem until you have more capacity.

Biopsychosocial Model Prevailing model of mental illness as a complex interaction of biology (genes and medical history), psychology (schemas, in our view), and society (one's support system and social models of how to respond to adversity) [91].

Contraindication Any medical condition, life circumstance, activity, or medication that makes MDMA use particularly risky.

Defense Cascade A series of physiological changes that prepares the body to respond to immanent threats [166]. Includes arousal, flight or flight, freezing, and immobility. Different situations and past experiences activate different responses.

Dissociation Emotional numbing caused by brain-produced opioids in response to perceived threat and powerlessness (usually a maladaptive schema when you're not in an acutely dangerous situation) [166, 172]. This can escalate to immobility and greater degrees of detachment from one's self and external reality.

Fight or Flight Active defense response characterized by high levels of adrenaline and muscle activation, increased heart rate, and decreased pain sensitivity [166].

Freeze A fight or flight response temporarily put on hold [166]. One remains highly attentive but frozen to avoid the notice of predators who are more likely to notice moving objects.

Grounding Techniques Activities that turn off or turn down defense cascade activations. These usually involve distraction (e.g. name all the round objects in the room), feelings of safety (e.g. vividly recalling memories of safety), or feelings of power (e.g. vividly constructing mental imagery of overcoming some adversity) [228]. As far as we can tell, they are not based in rigorous evidence, but people like them, they're easy, and they seem low-risk.

Mismatch The conscious contradiction of an active schema via either sensory input or another schema [85].

Non-dual Awareness Experiences of unity, without the usual separation into self and other [205]. We suspect that MDMA can produce states of partial non-dual awareness.

Predictive Processing The prevailing model of brain function [55]. The brain internally models the world (via complex layers of learned predictions) to better plan for the fulfillment of basic needs such as bodily integrity, reproduction, community, etc. Prediction error is a discrepancy between 1) the brain's model of the world and incoming sensory data, or 2) two contradictory model predictions [55]. Minimization of prediction error is the brain's core optimization function, achieved through the construction of more complex and accurate world-models.

Psychedelic Showing the Mind/Soul, from the Greek 'psyche' and 'deloun' [147]. Most are tryptamines, phenethylamines, and ergamides [127]. Among a variety of effects specific to each compound, they generally relax high-level predictions [48]. Psychedelic-Assisted Therapy uses this effect, and other effects specific to certain drugs (like MDMA's safety and empathy), to help change maladaptive predictions/schemas.

Psychogenic Illness Illnesses caused in large part by maladaptive schemas [133].

Reconsolidation When a schema/memory is first formed it is "consolidated [85]." When prediction error on that schema becomes large enough, the schema enters a mode where it is changeable. Maintaining that prediction error then updates the schema to reflect the new information. At the end of this process the schema "re-consolidates" and becomes unchangeable again. We use "reconsolidate" to denote this whole process of activation, updating, and reconsolidation.

Reconsolidation Exhaustion Emotional exhaustion and lack of energy follow successful reconsolidation (See Section 4.1). Often called therapy hangover. We think this is reliable enough to indicate that emotional exhaustion is a solid sign of therapeutic success. People seem to be capable of 1-2 hours of reconsolidation a day before exhaustion becomes so intense that the process is no longer possible.

Resistance Opposition to reconsolidation or a broader therapeutic process that would actually be healthy for the individual. This is difficult to ascertain, as many therapeutic processes are not actually a good match for many people.

Schema A single learned prediction (or prior) in the brain's world model [85]. What are called low-level (physically lower in the brain) schemas perform a vast array of functions relating to maintenance of basic bodily functions and sensory data processing [55]. Therapeutically-relevant schemas are generally more abstract, high-level predictions about the self, relationships, or whether the world is generally safe/predictable or not.

Selective Inhibition The suppression of all voluntary distractions, avoidance, and coping strategies to highlight maladaptive schemas [245]. Razvi proposes that this also facilitates a "completion" of the defense cascade cycle, but we are uncertain about this.

Spiritual Bypass The use of spiritual attainments, practices, or beliefs as reasons to not notice, investigate, or address one's maladaptive schemas [51].

Therapeutic Destabilization A period of instability experienced while transitioning from a stable state of mental illness to a stable state of mental health [226]. This should not be used as an excuse for unethical or unskilled behavior from therapists or guides.

Tonic/Collapsed Immobility Inactive defense responses characterized by detachment, emotional and physical numbing, and immobility [166]. Predators are more attracted to moving prey and may lose interest in seemingly-dead bodies. May escalate to unconsciousness.

Trauma We use two closely related definitions: 1) Events that lead to over-generalized schemas that impair functioning or emotional health. 2) Distressing events or chronic conditions that overwhelm our ability to cope, where our ability to cope depends on our capabilities and resources [171].

Window of Tolerance The range of dissociation, arousal, or fight-or-flight where reconsolidation is possible. High levels of these states often inhibit reconsolidation [245]. MDMA expands the window beyond what is usable in regular psychotherapy.

Appendix A

**Psychoeducation

In the course of researching this book, we've come across a number of interesting and/or helpful educational resources that may be relevant to the needs of therapeutic MDMA practitioners. Many have been individually helpful to us, or come recommended by trusted colleagues. Although we have not rigorously evaluated all these items, we chose to include them on the assumption that our readership (almost definitionally individuals who connect with written works on these topics) may find value in such a list.

- *Unlocking the Emotional Brain, Eliminating Symptoms at their Roots Using Memory Reconsolidation* This book may have popularized connection between [prediction](#) error, memory reconsolidation, and therapeutic improvement. We think it is so useful that it should be required reading for all mental health professionals. Ecker [\[84\]](#) provides a complementary resource addressing common misunderstandings and clarifies some fundamental mechanisms.
- *Good Inside*, by Dr. Becky Kennedy [\[159\]](#) is a book that illustrates calmly and thoroughly what it looks like when several of the healthiest and most "workable" schemas play out in a parenting realm, and compares them to common less workable alternatives. The author has elsewhere described this school of thought as "study parenting"—introducing parents to schemas and behavioral strategies that allow them to be sturdy leaders in a family setting. Many of the strategies focus on differentiating between parents' emotional support of children and parents' behavioral compliance with children's demands. Kennedy encourages parents to provide a basically unlimited amount of validation and witnessing of their children's struggles, and to develop robust emotional relationships in which they earn the trust to witness their children's inner worlds—while also illustrating clearly that this emotional intimacy and support not only *can* be paired with robust boundaries around children's behavior, but that both those boundaries and that validation are essential for cultivating children's experience of safety in the world and trust in themselves.

We find this book to be an excellent resource for parents and non-parents alike. It's true that the triggers of dysregulation will be different for non-parents than for the parents and young children who the book directly addresses. However, the basic behavioral patterns the book promotes are tremendously adaptive, and are adaptable to any kind

of relationship. Additionally, we suspect that working with this book may facilitate attachment healing through schema reconsolidation in the same vein as Ideal Parent Figure imagery.

- *The Upside of Stress* by Kelly McGonigal, Ph.D. McGonigal discusses how not all stress is harmful. Short-lived stress can foster resilience and growth. The book highlights the importance of mindset and provides tools to reinterpret stressors as growth opportunities [200].
- *The Body Keeps the Score* by Bessel van der Kolk, Ph.D. [311] ¹.
- *Don't Shoot the Dog* by Karen Pryor: [236].
- *Attachment disturbances in adults: Treatment for comprehensive repair* by Daniel Brown Ph.D. and David Elliott Ph.D. A great, though lengthy and dense, textbook for understanding and treating adult attachment disorders. It combines clinical insights with research findings and illustrative case studies [43].
- If you're interested in the general theory of predictions in the brain, we recommend two definitive books by Andy Clark, Ph.D. on hierarchical predictive processing. *The experience machine: How our minds predict and shape reality* is the less-technical mass-market version [55]. *Surfing uncertainty: Prediction, action, and the embodied mind* is the more technical, though not mathematical, of the two books [54]. S. Alexander [8] provides a good and accessible summary of it.
- *The science of trust: Emotional attunement for couples* by John Gottman, Ph.D. [122].

¹The details are not publicly available, but Bessel van der Kolk's former boss said he fired Bessel based on multiple employee reports of bullying [165]

Appendix B

**Shame Triggers Writing Exercise

This list was adapted from *I Thought It Was Just Me (but it isn't)* by Brené Brown Ph.D. [41]. We think it is another useful tool for uncovering maladaptive schemas. Complete the "I want to be perceived as" and "I don't want to be perceived as" prompts for each item. Feel free to add categories that are especially relevant to you.

- Appearance and body image
 - I want to be perceived as:
 - I want to be perceived as:
 - I want to be perceived as:
 - I don't want to be perceived as:
 - I don't want to be perceived as:
 - I don't want to be perceived as:
- Money and work
- Motherhood/fatherhood
- Family
- Parenting
- Mental and physical health (including ability and disability)
- Addiction
- Sex
- Aging
- Surviving Trauma
- Racial and Ethnic Identities
- Friendship

- Community membership
- Political activism/civic engagement/meaningful work/volunteering/calling
- Creative Life
- Gender
- Home/living situation

Appendix C

**Attachment Theory

Attachment theory is a model which posits that [secure attachments](#) formed in the first 18 months of life serve as the foundation for emotional and psychological development throughout one's life [43]. It is one of the most empirically supported theories in psychology, with over 70 years of well-replicated research behind it. According to attachment theory, the presence of consistent, sensitive caregiving facilitates the development of secure attachment—and in its absence, individuals tend to develop anxious, [avoidant](#), or disorganized styles of attachment. Researchers have identified five pillars of secure attachment. Cultivating secure attachment requires caregivers who are physically present, consistent, reliable, and interested in enacting these five pillars. That is to say—for the five pillars to be met, these additional conditions must also be met as their foundation. The five pillars are:

- **Felt Safety/Protection** The child knows the caregivers are on their side and will act in their best interest across many domains of life (physically, emotionally, etc.).
- **Feeling Seen and Known/Attunement** The child accurately feels that their caregivers actually know what is going on with them; caregivers encourage and value open communication, and are sensitive and responsive to a wide variety of cues from the child. Caregivers recognize and validate the child's separate experiences.
- **Felt Comfort/Soothing and Reassurance** Caregivers assist the child in accepting and regulating their emotions, and the child is able to feel calm when needed and able to feel appropriate distress without self-judgment or repression. Caregivers are available, responsive, and skilled at reassuring the child when the child is upset.
- **Feeling Valued/Expressed Delight** Caregivers express pleasure in the child's presence and satisfaction in their existence; caregivers are openly affectionate, loving, valuing, and caregiving towards the child on a consistent basis.
- **Felt Support for Best Self/Unconditional Support and Encouragement** Caregivers support the child in exploring the world away from the caregiver, and in interests and desires that are different from the caregiver's as well as those that are the same.

While the intention of the parent is important, the ultimate impact is based on how much the child feels these factors. The absence of these factors in early childhood often leads to

profound emotional pain and dysfunction later in life. For a more thorough discussion see section "Qualities Known in General to Promote Secure Attachment" on pages 323-325 of *Attachment Disturbances in Adults: Treatment for Comprehensive Repair* by Daniel Brown Ph.D. and David Elliott Ph.D. [43].

We also recommend:

- The Heidi Priebe Youtube channel, which offers an array of videos that provide practical advice on specific topics from a rich, rigorous, and nuanced attachment-based perspective [234].
- Theattachmentproject.com, which offers free access to an empirically validated instrument for assessing your attachment style (labeled there as a “quiz”) [296]. They also provides a list, based on the work of Dr. Jeffrey Young et al., of common maladaptive schemas caused by insecure attachment [297].
- Therapists Uncensored, a podcast where two therapists discuss many aspects of attachment theory with guests who include experts in the field [158].

Appendix D

**Self-Determination Theory

Self-Determination Theory (SDT) is a theory of human motivation and behavior, positing that people have innate psychological needs, and satisfying these needs leads to better mental well-being and performance [73]. Many studies across cultures, age groups, and domains (education, work, sports, health, etc.) have examined and supported its principles. We think contemplating how these needs have or have not been fulfilled in your life may uncover maladaptive schemas.

The three fundamental psychological needs identified in SDT are:

- **Autonomy** The need to feel in control of one's actions and choices. It's not about being independent, but rather about feeling that one's behavior is self-endorsed and congruent with personal values and interests.
- **Competence** The need to feel effective and capable in one's activities. It involves mastering tasks, gaining new skills, and feeling a sense of growth in one's capacities.
- **Relatedness** The need to feel connected to others, to care for and be cared for by others, and to feel that one belongs with others. It emphasizes the importance of relationships and emotional connections with peers, family, and the broader community.

For more information, see *The “What” and “Why” of Goal Pursuits: Human Needs and the Self-Determination of Behavior* by Edward Deci Ph.D. and Richard Ryan Ph.D. [73].

Appendix E

**Life Changes for Improved Mental Health

There is a great deal of low-quality evidence that a variety of lifestyle changes improve mental health. Almost none of this research involved adequately blinded trial participants, so the reported effects of any of these interventions could easily be nothing but bias. However, they are generally low-risk and well known to have other positive effects. Note that mental health is highly complex and situation-dependent and average effects in trials don't necessarily guarantee any particular intervention will help you with your particular solution.

Physical Habits:

- Stopping or reducing regular use of harmful substances.
- Physical activity has a significant improves mental health [255]. Additionally, aerobic exercise decreases the risk for many chronic illnesses [176] and whole-body muscle strengthening decreases risk of acute and chronic injuries [173]. We suggest Low [186] or working with a physical therapist.
- High sleep quality (defined as feeling well-rested in the morning, low number of awakenings, and quick sleep-onset) is important for mental health [271]. *Cognitive Behavioral Therapy for Insomnia* has excellent high-quality evidence. Stanford Medicine has a guide [287]. Melatonin is safe and might help [216]. It's efficacy for sleep disorders without comorbid mental illness is well-established, but it is poorly studied for sleep disorders caused by mental-illness. The UK National Health Service recommends starting with a 2mg extended/slow release pill taken 1-2 hours before bed [219].
- We are not aware of any quality evidence on the topic, but think it's plausible that air pollution worsens mental health. It causes a variety of other health problems [78]. Air filters can help. Clean Air Kits [58] or similar seems to provide some of the best cost, noise, and performance.

Relationships:

- Relationships improve mental and physical health [143]. The structure of our societies and culture often make forming healthy relationships difficult. We suggest making relationships a higher priority in your life through, for instance, co-living, co-working, volunteering, or seeking romantic, artistic, or business partnerships.
- Understanding when and why people change their minds about things may reduce unnecessary conflict and help you foster healthier beliefs in your community. We suggest *How Minds Change: The Surprising Science of Belief, Opinion, and Persuasion* by David McRaney.
- Emotional attunement is an important skill for trust in relationships [122]. See *The Science of Trust, Emotional Attunement for Couples* by John Gottman, Ph.D. It is useful for all kinds of close relationships, not just romantic couples.
- Accountability (and forgiveness if that feels right for you) for one's own and other's actions is important for healthy communities. We suggest Mingus [210], Barnard Center for Research on Women [25], and Gottman [122].

Introspection and Self-Improvement:

- Carefully consider the things you own. Which ones really make you happy? Which ones would you be better off without? Marie Kondo's methods for doing this are quite popular.
- There is low-quality evidence that journaling improves mental health [284].
- Mindfulness meditation improves mental health [125].
- Consider how you cope with stress. Which behaviors are healthy for you and those around you? Which aren't?

Appendix F

**Suggested Avenues of Future Research

Many recommendations for further research are well-understood. Here are a few that we think would be valuable but have not seen anywhere else:

- What factors improve reconsolidation (e.g. high quality sleep probably)?
- What is the nature of [reconsolidation exhaustion](#) (perhaps neurotransmitter depletion, limits on the neural protein-synthesis and gene expression pathways fundamental to memory reconsolidation, other limits on synapse formation, or the after-effects of high levels of stress hormones.)? Can the capacity be safely increased?
- MG and others (personal communications) have reported increased capacity to achieve reconsolidation while sober in a way that is phenomenologically and consequentially similar to what is experienced during MDMA-therapy sessions. This appears to be connected to extensive prior MDMA-therapy. How does this work? What are its effects? How can it be promoted? We suspect it is linked to deeply internalized [non-dual](#) awareness.
- Where does solo MDMA-therapy and professionally guided MDMA-therapy fit on the mental health treatment Pareto Frontier of cost, effectiveness, and safety?
- Why does MDMA seem to provide prediction error for most, if not all maladaptive schemas, but not the adaptive ones?
- How can therapists best prepare their clients for solo at-home sessions (e.g. for sex therapy)?
- Gain a better understanding of which side effects are part of the therapeutic process and which aren't.
